MacMONNIES, mȧk-mŭn′ĭz, FREDERICK (WILLIAM) (1863–). One of the foremost American sculptors of his day, also a painter of note. He was born in Brooklyn, Sept. 20, 1863. His father was of Scottish descent and his mother a niece of the American painter Benjamin West. At 17 he entered the New York atelier of Augustus Saint-Gaudens as an assistant, studying in the evening at the National Academy of Design and at the Art Students' League. In 1884 he went to Paris, to which, after a year spent in studying painting at Munich, he returned to enter the atelier of Falguière. Two years later he established an atelier of his own. His statue of Diana won honorable mention at the Salon of 1889. The statue of Nathan Hale, now in City Hall Park, New York, and that of James S. T. Stranahan, in Prospect Park, Brooklyn, were exhibited in the Salon of 1891 and brought him a second medal, the first time an American had been thus honored. The Hale statue admirably renders the lofty sentiment of the youthful patriot; the Stranahan is celebrated for the cleverness with which the details of silk hat and cane are managed. In the Salon of 1892 MacMonnies exhibited the little fountain figure called "Pan of Rohallion," and the "Boy with a Heron," the first of a series of fanciful bronzes of bewitching grace. The most important of his works, and the one which has done most to secure his reputation, was the colossal fountain in the Court of Honor at the Columbian Exposition (Chicago, 1893). In a wonderful decorative boat, propelled by eight stalwart oarswomen (the "Arts and Industries"), with "Fame" at the prow and "Father Time," "Columbia" sat enthroned—the whole being pronounced by competent critics the finest piece of sculpture on the grounds. In 1894–95 MacMonnies modeled the imposing monument at West Point. His statue of a nude Bacchante, exhibited in the Salon of 1894, was bought for the Luxembourg Gallery. The attempt to place a replica of this statue (now in the Metropolitan Museum, New York) in the court of the Boston Public Library excited much prudish criticism. MacMonnies' remarkable activity produced a statue of Sir Henry Vane (Boston Public Library); the Army and Navy groups for the Soldiers' and Sailors' Monument in Indianapolis; much work for the Congressional Library in Washington, including the central bronze doors and a statue of Shakespeare; and, his most extensive work in bronze, the sculptural decorations of the triumphal arch at the main entrance to Prospect Park, Brooklyn. These comprise three colossal groups in bronze: "The Army," a group of soldiers in active combat; "The Navy," a group of men standing in restrained and quiet poses; and, above, "America," in her chariot and heralded by winged victories. The two groups of athletes and horses at the southern entrance to Prospect Park are fine examples of park sculpture in bronze. Other noteworthy sculptures by MacMonnies are the statue of General Slocum (1900, Brooklyn); an equestrian statuette of Theodore Roosevelt (1905); equestrian statue of General McClellan (1906, Washington); the Pioneer monument at Denver. In 1903 he began to devote himself to painting. Of considerable merit are his impressionist portraits of the sculptor John Flanagan, the curé of Givernay, Georges Thesmar, and his first wife (see LOW, MARY FAIRCHILD) and his children. Yet it was fortunate that in 1913 he returned to sculpture. In this field alone his great talent, especially as a brilliant technician, is fully manifest. Besides other honors, he received a medal at the World's Fair, Chicago, in 1893, and a gold medal at Buffalo in 1901. He was made Chevalier of the Legion of Honor in 1898 and won a grand prize of honor at the Paris Exposition of 1900, was elected to the National Academy of Design in 1906, and became a member of the National Institute of Arts and Letters. Consult: Greer, in *Brush and Pencil* (Chicago, 1902); the admirable chapter "MacMonnies," in Lorado Taft, *History of American Sculpture* (New York, 1903); and, for his portrait painting, Pettie, in the *International Studio*, vol. xxix (ib., 1906).

MACMUL'LEN, WALLACE (1819–99). An Irish Wesleyan Methodist preacher, born in the Ards, County Down. Accepted as a candidate for the ministry in 1840, for years he labored in some of the hardest circuits. In 1859 he became connected with the home-mission board of the Irish Wesleyan Conference, and in its interest he continued to labor until his death, with the exception of five years. For the last 20 years of his life he was general secretary of the home-mission fund. In 1876 he was the leader of a group of men who were the authors of the plan for lay delegation subsequently adopted by the conference, and he was also a leader in the movements culminating in the consolidation of Irish Methodism. He was frequently a representative to the British Conference; was elected to the Legal Hundred in 1871 and served four times as vice president; was fraternal delegate to the General Conference of the Methodist Episcopal Church in 1880, and also represented the British and Irish conferences at the General Conference of the Methodist Church in Canada; was a member of the Ecumenical Methodist Conference of 1881; and for many years served as the chairman and treasurer of the Wesley College committee. During much of his life he resided in Dublin, and it was there that he died. Widely known as an eloquent speaker, he was in much demand for great occasions. His brother came to the United States and was for many years a pastor in the New York East Conference of the Methodist Episcopal Church. For his nephew, see the following article.

MACMULLEN, WALLACE (1860–). An American Methodist Episcopal theologian. He was born in Dublin, Ireland, a nephew of the noted Irish Wesleyan Methodist minister of the same name. Early coming to the United States, he graduated from Drew Theological Seminary in 1888 and entered the ministry in the same year. He was pastor successively of a Methodist church at Springfield, Mass., Grace and Park Avenue churches, Philadelphia, and the Madison Avenue Church, New York. In 1913 he was elected professor of homiletics in Drew Seminary. He is author of *The Captain of our Faith* (1904) and *The Child and the Kingdom* (1907).

MacMUR'RAY, JOHN. See MURRAY, JOHN.

McMURRICH, măk-mŭr'ĭk, JAMES PLAYFAIR (1859–). A Canadian anatomist, who for many years was resident in the United States. He was born in Toronto, Canada, graduated from the University of Toronto in 1879, and in 1885 took his Ph.D. at Johns Hopkins, where he was an instructor in mammalian anatomy in 1884–86. He served as professor of biology at Ontario Agricultural College (1882–84), at Haverford (1886–89) and at Cincinnati (1892–94), as docent and assistant professor of animal morphology at Clark University (1889–92) and as professor of anatomy at the University of Michigan (1894–1907) and at Toronto after 1907. He was also an instructor at Woods Hole, Mass., in 1887–91, and served as president of the American Society of Naturalists in 1907 and of the American Association of Anatomists in 1908. He published *A Textbook of Invertebrate Morphology* (1894; 2d ed., 1896) and *The Development of the Human Body* (1902; 4th ed., 1913), and edited Sobotta's *Atlas and Textbook of Human Anatomy* (1906–07) and Morris's *Human Anatomy* (1907).

MACMURROUGH, măk-mûr′rŭᴋ, Dermot (Diarmait mac Murchadha) (c.1110–71). King of Leinster in Ireland from c.1135 to 1171. In 1166, being driven out by O'Ruairc, Lord of Breifne, whose wife he had abducted 14 years before, he fled to England and appealed to Henry II for aid. Henry was unable to go to Ireland in person, but authorized any of his subjects to do so. Richard of Clare, called Strongbow, was the chief leader of the force of adventurers that invaded Ireland and established themselves in the eastern part of the island (see Ireland); he afterward married Dermot's daughter. Dermot was successful for a time and hoped to conquer all Ireland. Consult F. P. Barnard (ed.), *Strongbow's Conquest of Ireland* (New York, 1888), and H. W. C. Davis, *England under the Normans and Angevins* (New York, 1905). See Henry II, King of England.

McMUR′RY, Charles Alexander (1857–). An American educator, a brother of Frank Morton McMurry. He was born at Crawfordsville, Ind., graduated at the Illinois State Normal University in 1876, and studied at the University of Michigan (1876–80) and at Halle (Ph.D., 1887) and Jena. After teaching for several years, he was principal of the practice school of the Illinois State Normal University (1899–1900), and held a similar position at the Northern Illinois Normal School (1900–01). His works include: *The Elements of General Method* (1892; 6th ed., rev., 1903); *Method of the Recitation* (1898), with F. M. McMurry; *Special Method of Reading* (1898; new ed., 1910); *Special Method in Literature and History* (1898); *Special Method in Geography* (1898); *Special Method in Natural Science* (1896; 2d ed., 1899); *Pioneer History Stories* (3 vols., 1891; 5th ed., 1898); *Special Method in Primary Reading and Oral Work* (1903); *Special Method in Reading in the Grades* (1908); *Handbook of Practice for Teachers* (1914); *Conflicting Principles of Teaching and How to Adjust them* (1915).

McMURRY, Frank Morton (1862–). An American educator, a brother of Charles Alexander McMurry. Born near Crawfordsville, Ind., he studied at the University of Michigan and afterward at Halle and Jena (Ph.D., 1889) and in Geneva and Paris (1892–93). He was professor of pedagogics and training at the Illinois State Normal University in 1891–92, and subsequently professor of pedagogy at the University of Illinois (1893–94), principal of Franklin School, Buffalo (1894–95), and dean of Teachers College, University of Buffalo (1895–98). In 1898 he was appointed professor of elementary education at Teachers College, Columbia University. With Ralph S. Tarr he published the *Tarr and McMurry Common School Geographies* (1900), and with C. A. McMurry *Method of the Recitation* (1903). He is sole author of *How to Study and Teaching How to Study* (1909) and *Elementary School Standards* (1913).

McMUR′TRY, Lewis S. (1850–). An American surgeon. He was born at Harrodsburg, Ky., and studied at Centre College in his native State (A.B., 1870) and at Tulane University, New Orleans (M.D., 1875). Establishing himself in practice in Louisville, he became professor of gynecology and abdominal surgery in the university of that city. In 1905 he was president of the American Medical Association. Tulane gave him an honorary LL.D. in 1909. Besides contributing to medical journals, McMurtry published a *Textbook of Surgery* and contributed to the *International Textbook of Surgery.*

MacNAB′, Sir Allan Napier (1798–1862). A Canadian political leader and soldier, born at Newark (now Niagara), Ontario. He entered the British navy as a midshipman in 1813. Leaving the navy, he became an ensign in the army, served throughout the War of 1812–15, and took part in the actions at Fort Erie and Black Rock and commanded the advance at the battle of Plattsburg. At the close of the war he remained in Canada, studied law, and was admitted to practice at the Canadian bar in 1826. He was elected to the Upper Canada Legislative Assembly in 1830 and was Speaker of that body in 1837–41. He was prominent in sustaining the government against Mackenzie's insurrection in 1837–38. While he was in command at Niagara the steamer *Caroline,* employed by American sympathizers to assist the rebels, was, by his order, seized, fired, and sent over Niagara Falls. (See Caroline, The.) MacNab was rewarded by being knighted. After the union of Upper and Lower Canada in 1841 he was leader of the Conservative Opposition until 1844, Speaker of the Legislative Assembly (1844–48), and in the latter year again Speaker of the Assembly. In 1854–56 he was Premier of Canada, his colleague, A. N. Morin, being the chief representative of Lower Canada in the cabinet. Its leading member was, however, Mr. (afterward Sir) John A. Macdonald; and it was mainly through the latter's efforts that a measure abolishing the clergy reserves was passed (1854). MacNab retired from the leadership of the Conservatives in 1857 and went to England. In 1858 he was made a baronet, and in 1860, on his return to Canada, he became a member of the Legislative Council, of which he was elected Speaker in 1862.

MACNAGHTEN, m*a*k-na̤′t*e*n, Edward, first Baron (1830–1913). A British jurist, born in County Antrim, Ireland. He was educated at Trinity College, Cambridge (M.A.); studied law at Lincoln's Inn, where he became a barrister and bencher; subsequently he was made queen's counsel. He served in Parliament in 1880–87, was appointed Lord of Appeal-in-Ordinary in 1887, and was created a baron in the same year. For many years before his death he had been one of the most prominent figures on the bench.

McNAIR′, Frederick Vallette (1839–1900). An American naval officer, born at Jenkintown, Pa. Graduating from the United States Naval Academy in 1857, he became a lieutenant in 1861, lieutenant commander in 1864, commander in 1872, captain in 1883, and rear admiral in 1898. During the Civil War he participated in many important engagements, first on the *Iroquois* (1861–62) and afterward on the *Juniata*

(1862–63, 1864–65) and the *Seminole* (1863–64). In 1875–78 he commanded the *Kearsarge* on the Asiatic Station and in 1887–89 he had command of the *Omaha*. In 1890 he became superintendent of the Naval Observatory, in 1895 commander in chief of the Asiatic Station, and in 1898 superintendent of the Naval Academy. While serving in the last-named capacity he was given charge of Admiral Cervera and other distinguished prisoners of the Spanish-American War.

MACNAMARA, măk′nȧ-mä′rȧ, Thomas James (1861–). A British educator and politician. He was born in Montreal, Canada, but early went to England. After a course at the Borough Road Training College for Teachers, London, he taught (1876–92); was editor of the *Schoolmaster* (1892–1907); served on the London school board (1894–1903); and in 1896 was president of the National Union of Teachers. He was elected to Parliament as Liberal member for North Camberwell in 1900, and in 1906 played a conspicuous part among the supporters of the Liberal government's Educational Bill. He became parliamentary secretary to the Admiralty in 1908 and Privy Councilor in 1911. He published: *Schoolmaster Sketches* (1896); *Schools and Scholars* (1900); *School-Room Humour* (1905); *The Gentle Golfer* (1906); *Tariff Reform and the Working Man* (1910).

MacNAUGHTON, mak-nạ′ton, Myra Kelly. See Kelly.

MacNEIL, măk-nēl′, Hermon Atkins (1866–). An American sculptor. He was born at Chelsea, Mass., and studied at the Massachusetts Normal Art School in Boston and under Chapu and Falguière in Paris. On his return to America he was awarded the designer's medal for his work at the Columbian Exposition (1893). His bronze reliefs of the life and death of Père Marquette (Marquette Building, Chicago) are the first of a series of Indian subjects for which he has become famous. In 1896 he won the Rinehart scholarship and spent four years of study in Rome; in 1900 he aided in the decoration of the American pavilion at the Paris Exposition, and in 1904 modeled the main fountain at the St. Louis Exposition. He made his home on Long Island. His art is typically American. His figures and groups are admirably modeled and compactly constructed, yet possess charming elaboration of detail. The best of his Indian subjects are "Sun Vow," modeled at Rome (privately owned; smaller replicas in the Metropolitan Museum and Corcoran Gallery, Washington); "Primitive Chant" (Peabody Institute, Baltimore, and Metropolitan Museum, New York); "The Coming of the White Man," a group in the City Park, Portland, Oreg.; "The Moqui Prayer for Rain," statuette (Art Institute, Chicago). Proof of his great versatility is furnished by the relief "From Chaos Came Light"; the McKinley Memorial (1907, Columbus, Ohio); the Platt Memorial, State Capitol, Hartford; the Soldiers' and Sailors' Memorials at Whitinsville, Mass., and Albany, New York; the ideal works "Repose" and "Inspiration" (1912); and the three powerful female busts "Agnes" and "Beatrice" and that of Miss Longman, the sculptor. MacNeil received many awards, including gold medals at Buffalo (1901), Charleston (1902), St. Louis (1904), and Buenos Aires (1910).

His wife, Carol Brooks MacNeil (1871–), was born in Chicago and studied there at the Art Institute under Taft and in Paris under MacMonnies and Injalbert. She modeled many charming and unique designs for vases, teapots, inkstands, and other decorative and useful objects, as well as children's busts, including those of her two sons, and statuettes.

McNEILE Hugh (1795–1879). A British churchman. He was born at Ballycastle, County Antrim, Ireland; graduated at Trinity College, Dublin, in 1815; and early studied law. After 1820 he held various curacies, St. Paul's Church, Liverpool, being built for him. In 1845 he was appointed canon of Chester Cathedral, and in 1860 canon residentiary. He became dean of Ripon in 1868, but resigned from that position in 1875 and retired to Bournemouth. Although at one time inclined to embrace the doctrines of Edward Irving (q.v.), he afterward reviewed them severely in three sermons on *Miracles* (1831–32) and in *Letters to a Friend who had Felt it his Duty to Secede from the Church of England* (1834). Other works are: lectures on *The Prophecies Relative to the Jewish Nation* (1830); *The Church of England* (1840); *The Sympathies, Sufferings, and Resurrection of the Lord Jesus Christ* (1843); *Sermons on the Second Advent of Christ* (1865); *Letters on the Athanasian Creed* (1873); *Scripture Proportions* (1873). His collected works began to appear in 1877. Consult *Hugh McNeile and Reformation Truth* (London, 1882).

McNEILL, John (1854–). A British Presbyterian preacher, born in Houston, Renfrewshire, the son of a quarry foreman. From 1869 to 1877 he was a railway employee, and then studied for the ministry at Edinburgh and Glasgow universities and at the Free Church Divinity Hall in Glasgow. In 1886–89 he preached in Edinburgh and then for three years at the Regent Square Presbyterian Church in London. In 1892 he joined D. L. Moody as a revival preacher in Aberdeen and during the next six years conducted mission services in many different parts of the world. He became pastor of these Presbyterian churches: Christ, Westminster Bridge Road, London (1908); St. George's, Liverpool (1910); Cook's, Toronto, Canada; and the Central, Denver, Colo. (1915).

MacNEVIN, William James (1763–1841). An American physician. Born at Ballynahowne, County Galway, Ireland, he was sent when 12 years old to Vienna, where his uncle, Baron O'Kelly MacNevin, was physician to the Empress Maria Theresa. He received his medical training at Prague and Vienna (M.D., 1784) and then returned to Ireland. As one of the leaders of the United Irishmen he was kept in prison from 1798 to 1802. After his release he served for three years in the French army, and in 1805 he came to the United States. At the College of Physicians and Surgeons, New York, where he became professor of obstetrics in 1808 and professor of chemistry and materia medica in 1811, he was the first to open a chemical laboratory. Resigning his chair in 1826, he joined Valentine Mott (q.v.) in establishing a new medical school, but this existed only four years. MacNevin was the author of *Rambles through Switzerland* (1803); *Pieces of Irish History* (1807), with Thomas Addis Emmet; *Chemical Examination of the Mineral Waters of Schooley's Mountains* (1815); *Exposition of the Atomic Theory of Chemistry* (1819). He also served as associate editor of the *Medical and Philosophical Journal* (New York).

MACOMB, mȧ-kōm′. A city and the county seat of McDonough Co., Ill., 59 miles northeast of Quincy, on the Chicago, Burlington, and Quincy Railroad (Map: Illinois, C 5). It is the seat of the Western Illinois State Normal School, and has a Carnegie library, high school, and three large hospitals. The surrounding agricultural region is productive, and the city has extensive manufactures of stoneware, bricks, foundry products, and sewer pipe. The vicinity abounds in clay. Settled about 1840, Macomb was incorporated in 1857. Under a charter of 1872 the government is vested in a mayor, biennially elected, and a city council. The water works are owned by the municipality. Pop., 1900, 5375; 1910, 5774. The city was named after General Macomb, who distinguished himself in the battle of Plattsburg. See PLATTSBURG.

MACOMB, ALEXANDER (1782–1841). An American soldier, prominent in the War of 1812. He was born in Detroit, Mich., entered the United States army as a cornet of cavalry in 1799, and by 1812 had risen to be lieutenant colonel of engineers and adjutant general of the army. Soon after the outbreak of the War of 1812 he was transferred to the artillery at his own request, and in 1813, as colonel of the Third Artillery, distinguished himself at Fort Niagara and Fort George. In January, 1814, he was promoted to be brigadier general and placed in command of the northern frontier, along Lake Champlain, and on September 11 of this year, while McDonough was defeating the English fleet in Plattsburg Bay, he defended Plattsburg, N. Y., against the attack of a greatly superior English force under Sir George Provost. In recognition of his services on this occasion he was promoted to be major general, and received a vote of thanks and a medal from Congress. After the war he continued in the service as colonel of engineers, and from 1828 until his death was the commanding general of the United States army. He published *A Treatise on Martial Law and Courts-Martial as Practiced in the United States* (1809) and *A Treatise on the Practice of Courts-Martial* (1840). Consult Richards, *Memoir of Alexander Macomb* (New York, 1833).

MÂCON, mȧ′kôɴ′. The capital of the Department of Saône-et-Loire, France, in Burgundy, 45 miles north of Lyons, on the Saône, which is here spanned by a bridge of 12 arches to the suburb, St. Laurent (Map: France, N., K 6). It has the ruins of the cathedral of St. Vincent, begun in the thirteenth century, and the modern church of St. Pierre, a large edifice in the Romanesque style. Mâcon trades extensively in agricultural products, has important watchmaking establishments, and manufactures copper and bronze ware, machinery, tools, paper, and oil; it is best known, however, as a centre of the Burgundy wine industry. Mâcon is the ancient Matisco, a town of the Ædui. It is the birthplace of the poet, Lamartine. Pop., 1901, 18,928; 1911, 19,851.

MACON, mā′kon. A city and the county seat of Bibb Co., Ga., 93 miles by rail southeast of Atlanta, on the Ocmulgee River, and on the Southern, the Central of Georgia, the Georgia Southern and Florida, the Macon, Dublin, and Savannah, the Georgia, and the Macon and Birmingham railroads; and there is steamboat connection with Brunswick and Savannah (Map: Georgia, C 3). It is the seat of Mercer University (Baptist), St. Stanislaus College (Roman Catholic), Wesleyan Female College, chartered in 1836, Mount de Sales Academy (Roman Catholic), the State Academy for the Blind, Ballard Normal School (colored), Central City College (colored), and several orphan schools. There are two public libraries, a United States government building, a fine city hall, United States Weather Bureau station, an Academy of Music, armories, and Central City, Tatnall Square, and Crumps parks. The Indian mounds in the vicinity are also of interest. The city is in a rich agricultural, fruit-growing, and cotton-raising region; has an extensive trade in cotton, lumber, and general merchandise; and its manufacturing industries are represented by large cotton and knitting mills, the shops of four railroads, employing almost 2000 men, brick factories, lumber mills, foundries and machine shops, flouring mills, etc. Excellent water power is afforded by a $3,000,000 dam, 30 miles above Macon, on the Ocmulgee River. Macon was incorporated as a town in 1823, having been settled shortly before, and in 1832 received a city charter. Its present government is administered under a charter of 1914, which provides for a mayor and a council of 12 members, chosen biennially, and two commissions, each of three members elected by the people, which control the police and fire departments and the water-works system. The water works are owned by the city. Macon's income in 1912–13 was $1,142,000, while its payments amounted to $1,164,000, the principal items of expense being $115,000 for education, $75,000 for police department, $89,000 for fire department, and $54,000 for the water-supply system. Pop., 1900, 23,272; 1910, 40,665; 1914, 41,992; 1920, 52,995.

MACON. A city and the county seat of Macon Co., Mo., 70 miles west by south of Quincy, Ill., on the Chicago, Burlington and Quincy and the Wabash railroads (Map: Missouri, D 2). It has the county insane asylum, Western College, an osteopathic sanitarium, a high school, a fine courthouse, and private educational institutions. The city is the centre of a fertile agricultural district having coal and timber, and there are coal mines, flour mills, creameries, carriage and wagon factories, foundries and machine shops, and manufactories of shears, dishwashing machines, cement blocks, cigars, etc. The water works and electric-light plant are owned by the municipality. Pop., 1900, 4068; 1910, 3584.

MACON, NATHANIEL (1758–1837). An American political leader. He was born of Huguenot parentage at Macon Manor in Warren County, N. C., Dec. 17, 1758; studied at the College of New Jersey (Princeton) from 1774 to 1776; served in the summer of 1776 in a company of New Jersey militia; returned home in the fall, and devoted the next three years chiefly to reading law and English history. In 1780 he joined a company of North Carolina militia under Major Benjamin Seawell and fought in the battle of Camden. The same year he was elected to the State Senate, in which body, taking his seat in June, 1781, and serving until December, 1785, he was a leading promoter of several reform measures, and a particularly persistent advocate of a metallic currency. In 1786 Macon was elected a delegate to the Continental Congress, but declined to take his seat, preferring State to national service. He belonged to the party which in 1788 vigorously opposed the ratification of the Federal

Constitution, but when, a year later, that party had become unpopular in his section of the State, he acquiesced, and, having been elected the first member from his district to a seat in the national House of Representatives, he served there continuously from 1791 to 1815, and was Speaker of the House from December, 1801, to October, 1807. He speedily became the recognized leader of the North Carolina delegation, was a severe critic of Hamilton's administration of the Treasury, advocated the increase of the United States naval force to overpower the Barbary pirates, and was one of the stanchest opponents of the bill providing for the execution of Jay's Treaty. He pleaded that the Sedition Law was unconstitutional and in so doing laid down the ultra States' rights doctrine that "This government depends upon the State Legislatures for existence. They have only to refuse to elect State Senators to Congress and all is gone."

As Speaker, Macon was a stanch supporter of Jefferson's first administration except that at its close he began, through the influence of John Randolph, to suspect that Madison, the Secretary of State, was implicated in the Yazoo frauds. At the beginning of Jefferson's second administration Macon reappointed Randolph, who had lost prestige with his party, chairman of the Committee on Ways and Means, and after Randolph refused to bring in a bill, upon the President's recommendation, for the purchase of Florida, Macon, Randolph, and Joseph H. Nicholson became leaders of a faction known as the "Quids," who directed their main efforts towards making Monroe, instead of Madison, the next President. Macon, also, in the interest of the agrarian supremacy of the South and consistently with his doctrine of State sovereignty, opposed the bill for abolishing the foreign slave trade, and continued his strenuous opposition to measures for the protection of trade and the defense of the coast other than by gunboats. He broke with Randolph in 1807 and returned to the support of Jefferson, the embargo, and the bill for a larger army. He seems to have coöperated with Madison and Gallatin in framing the "Macon Bill No. 1" for the exclusion of foreign war vessels from United States ports, for the suppression of illicit trade carried on by foreign merchants under the United States flag, for prohibiting the importation of goods from England or France except directly from those countries or in vessels manned wholly by citizens of the United States, and for authorizing the President to suspend these regulations in favor of either belligerent that should cease hostilities towards the trade of the United States. The bill passed the House in January, 1810, but was defeated in the Senate. "Macon's bill No. 2," which became a law in May, 1810, and provided for the repeal of the Nonintercourse Act of 1809, was Macon's only in name, its author being John Taylor, of South Carolina; and Macon voted against its final passage because of a protective clause which it contained. He voted, in June, 1812, for the declaration of war against Great Britain, and was made chairman of the committee of Congress to report on the enemy's "spirit and manner" of warfare. When peace had been restored he was opposed to the maintenance of a large standing army, saying: "The true way to safety is the militia, and the way to make our militia efficient is to let them know that the safety of the nation depends on them."

In December, 1815, Macon was elected to the United States Senate, where he served until 1828, the last two years as president pro tem. Advocating a "hard-money" currency, he voted against the bill for reëstablishing the National Bank, and continued to the close of his public life a firm believer in the "old Republican doctrines," too much so to be an administration leader under President Monroe. In 1824 he received Virginia's vote for the vice presidency. Macon retired from the Senate in 1828 of his own accord, and until his death, June 29, 1837, lived in seclusion on his plantation, except that in 1835 he served as chairman of the North Carolina Constitutional Convention and in 1836 was a presidential elector. In 1830 Randolph-Macon College was named for him and John Randolph. Consult: E. M. Wilson, *The Congressional Career of Nathaniel Macon* (Chapel Hill, N. C., 1900), and W. E. Dodd, *The Life of Nathaniel Macon* (Raleigh, N. C., 1903).

MACORIS, mȧ'kṓ'rēs'. A seaport of the Republic of Santo Domingo, situated on the south coast of the island of Haiti, on the Bay of Dos Ríos, 43 miles east of Santo Domingo. It has a number of sugar factories and carries on an active import and export trade. It is the seat of a United States consular agent. Pop., 7000.

MACOUN, mȧ-ko͞on', JOHN (1832–). A Canadian naturalist, born and educated in Ireland. He came to Canada in his nineteenth year, and in 1868 was appointed professor of botany and geology in Albert College, Belleville, but resigned in 1879 to accept government work in connection with an expedition to ascertain the natural resources of part of the Northwest Territories. Subsequently he was employed by the Canadian government in other scientific work in his department. In 1882 he was appointed botanist to the Geological and Natural History Survey of Canada, and in 1887 was made assistant director of the survey. He prepared several valuable catalogues of Canadian plants and birds for the Geological Survey. Several foreign and Canadian learned societies admitted him to honorary membership. In addition to numerous scientific papers and reports he wrote: *Manitoba and the Great Northwest* (1882); *The Forests of Canada and their Distribution* (1895); *Report on the Yukon Country* (1902).

MACOYA, mȧ-kō'yȧ, or MACAHUBA PALM. A kind of palm. See MACAW TREE.

MACPHAIL, mak-fāl', ANDREW (1864–). A Canadian physician, author, and editor. He was born at Orwell, Prince Edward Island, and was educated at Prince of Wales College, Charlottetown, and at McGill University. After a medical course at McGill and further study in London, England, he returned to Canada and was professor of pathology in the University of Bishop's College, Lennoxville, until 1907, when he became professor of the history of medicine in McGill University. He served as pathologist to the Western Hospital and the Protestant Hospital for the Insane (1895–1906). Besides his professorial duties at McGill, he practiced his profession and found time for literary work. In 1910 he became a fellow of the Royal Society of Canada and in 1911 a member of the Fleming Electoral Reform Committee (Canadian Institute). He wrote *Essays in Puritanism* (1905), *The Vine of Sibmah* (1906), *Essays in Politics* (1909), and *Essays* *in Fallacy* (1910); and edited the *Montreal Medical Journal* and the *University Magazine.*

MacPHEE, John Joseph (1860–). An American neurologist. He was born in Prince Edward Island, Canada; graduated from the medical department of the University of Vermont in 1890; and, settling in New York City, became neurologist to several hospitals, clinical professor of neurology at the New York Polyclinic Medical School, and later professor of nervous and mental diseases at the New York Postgraduate Medical School and Hospital. He contributed numerous articles to medical journals.

McPHER′SON. A city and the county seat of McPherson Co., Kans., 128 miles west by south of Topeka, on the Chicago, Rock Island, and Pacific, the Missouri Pacific, the Union Pacific, and the Atchison, Topeka, and Santa Fe railroads (Map: Kansas, E 6). It has McPherson College (German Baptist), Central Academy, a fine courthouse, Carnegie library, and a city park. The city is the commercial centre for an agricultural, dairying, and stock-raising region, and has grain elevators, flour mills, etc. McPherson adopted the commission form of government in 1914. The water works and electric-light plant are owned by the municipality. Pop., 1900, 2996; 1910, 3546.

MACPHERSON, Sir David Lewis (1818–96). A Canadian statesman, born Sept. 12, 1818, at Inverness, Scotland. Emigrating to Ontario in 1835, he entered a firm of railroad contractors and was subsequently president of the Interoceanic Railroad Company, which undertook to build a railroad through British Columbia, but the contract was given to the syndicate headed by Sir Hugh Allan. Having been a member of the Legislative Council of Canada from 1864 to 1867, he was called (1867) to the Dominion Senate, of which he was elected Speaker in 1880. In 1883 he resigned to become a member of the cabinet without portfolio, and in the same year he was appointed Minister of the Interior, a position which he held till 1885. For his services he was knighted in 1884. His publications consist of pamphlets relative to finance, such as *Banking and Currency* (1869). He died Aug. 16, 1896.

McPHERSON, Edward (1830–95). An American journalist, born at Gettysburg, Pa., where he studied at Pennsylvania College, graduating in 1848. After giving up the study of law he entered newspaper work. Becoming prominently identified with the organization in 1856 of the new Republican party at Harrisburg, where he lived, in 1858 and again in 1860 he was elected to Congress. He was Deputy Commissioner of Internal Revenue for a short time; clerk of the National House of Representatives (1863–73; 1881–83; 1889–91); permanent president of the Republican National Convention in 1876; and chief of the Bureau of Engraving and Printing (1877–78). For two years he was editor of the Philadelphia *Press.* He became editor of *The Handbook of Politics* in 1872, and from 1877 until his death was editor of the *New York Tribune Almanac.* He was also a political editorial writer on the *Tribune.* He published *A Political History of the United States during the Great Rebellion* (1865) and *A Political History of the United States during Reconstruction* (1870).

MACPHERSON, James (1736–96). "Translator" of the Ossianic poems, born at Ruthven, Inverness-shire, Scotland, Oct. 27, 1736. After finishing his studies at King's College, Aberdeen, he became a schoolmaster in his native village, published a poem entitled *The Highlander* in 1758, and in the following year, having met Dr. Alexander Carlyle, of Inveresk, and John Home, the author of *Douglas,* he showed them some fragments of Gaelic verse, of which he also gave them "translations." These "translations," 16 in number, appeared in 1760 under the title *Fragments of Ancient Poetry Collected in the Highlands.* They awakened so much attention that the Faculty of Advocates in Edinburgh raised a subscription to enable Macpherson to make a tour through the Highlands for the purpose of collecting more ancient Gaelic poems. The result was the publication in London of alleged translations of the poems of Ossian, bearing the titles *Fingal: An Epic Poem, in Six Books* (1762) and *Temora: An Epic Poem, in Eight Books* (1763). A storm of controversy arose in regard to their genuineness. Blair defended their authenticity; Dr. Johnson called for the Gaelic manuscripts, which were not forthcoming. Scholars are now agreed that though the so-called Ossianic poems are largely the work of Macpherson, yet they have a real basis in Gaelic legend. As a substantial result of his fame, Macpherson was appointed secretary to the Governor of Pensacola, West Florida, (1764), and London agent to the Nabob of Arcot (1781). He entered Parliament in 1780 as member for Camelford, sat for 16 years, and then retired to an estate which he had purchased in Inverness-shire, where he died Feb. 17, 1796. He wrote several historical works, notably *Original Papers, Containing the Secret History of Great Britain from the Restoration to the Accession of the House of Hanover, etc.* (1775). A staunch defender of Lord North's government, he drew a regular salary for his services in that connection. In accordance with his request his body was interred in Westminster Abbey. For the widespread interest in Macpherson's translations and their immense influence on literature, consult H. A. Beers, *English Romanticism* (New York, 1898), and Rudolph Tombo, Jr., *Ossian in Germany* (ib., 1905); for their relation to their originals, *Dean of Lismore's Book,* edited by MacLaughlan, with introduction by Skene (London, 1862), and *Poems of Ossian,* with translations by Clerk (Edinburgh, 1870). Consult also: *Poems,* translated by Macpherson, with introduction edited by Todd (London, 1888); *Life and Letters,* by Saunders (ib., 1894); A. Nutt, *Ossian and the Ossianic Literature* (ib., 1899), with important bibliographical appendix; J. S. Smart, *James Macpherson: An Episode in Literature* (ib., 1905). See Ossian.

McPHERSON, James Birdseye (1828–64). An eminent American soldier, prominent on the Federal side in the Civil War. He was born in Sandusky, Ohio; graduated first in his class at West Point in 1853, having as classmates such men as Philip H. Sheridan, John B. Hood, and John M. Schofield; and was appointed to the Corps of Engineers, with the rank of brevet second lieutenant. For a year after his graduation he was assistant instructor of practical engineering at the Military Academy, and was next engaged from 1854 to 1857 as assistant engineer upon the defenses of the harbor of New York and the improvement of Hudson River. In 1857 he superintended the building of Fort Delaware, and in 1857–61 was superintending engineer of the construction of the defenses of Alcatraz Island, at San Francisco, Cal. Upon the outbreak of the Civil War he was assigned to duty at Boston, where he raised a force of engineers; and in August, 1861, he was promoted to be captain of engineers. The following November he was made aid-de-camp to General Halleck and assistant engineer of the Department of the Missouri, with the rank of lieutenant colonel. From February to April, 1862, he served as chief engineer on the staff of General Grant, taking part in the capture of Fort Donelson and in the battle of Shiloh. In May, 1862, he was appointed brigadier general of volunteers and colonel in the regular army. He was with Halleck at the siege of Corinth; and when, after its capture by the Federal forces, the Confederates under Van Dorn and Price attempted to retake it in October, 1862, McPherson succeeded in penetrating their lines and reënforcing Rosecrans, who was holding the place with a force much inferior to that of the Confederates. For his services at Corinth McPherson was made major general of volunteers, Oct. 8, 1862. In December he was put at the head of the Seventeenth Corps, and had a distinguished share in Grant's Mississippi campaign, which terminated in the surrender of Vicksburg. After the fall of Vicksburg McPherson was, upon the recommendation of General Grant, appointed a brigadier general in the regular army and commander of the District of Vicksburg. In February, 1864, he was second in command to Sherman in the latter's expedition to Meridian, and on March 12 was made commander of the Department and Army of the Tennessee. In that command he maintained the reputation he had won in Mississippi, and rendered valuable service, during Sherman's campaign in Georgia. The Army of the Tennessee engaged the Confederates at Resaca May 14 and 15 and at Dallas May 28, 1864; and on June 27 McPherson aided Thomas in an unsuccessful assault upon Johnston's position at Kenesaw Mountain. Shortly thereafter he was engaged in the series of conflicts around Atlanta, in one of which, on July 22, 1864, he was killed while making a reconnoissance. General Grant, in a letter recommending him for promotion in 1863, praised him as "one of the ablest engineers and most skillful generals," and in his *Personal Memoirs* says: "In the death of McPherson the army lost one of its ablest, purest, and best generals."

McQUAID, m'-kwād′, Bernard John (1823–1909). An American Roman Catholic bishop. Born in New York City, he studied at Chambly College, near Montreal, and then entered St. John's College at Fordham, N. Y., where he graduated in 1843. Upon being ordained a priest in 1848, he was sent to South Orange, N. J., to found Seton Hall College and Seminary. Of this institution he was president for 10 years, during part of this time being also rector of the Newark Cathedral. In 1868 he was consecrated first Bishop of Rochester, N. Y. He devoted himself especially to the organization of parochial schools, lecturing and writing much on the subject.

MACQUARIE, mȧ-kwŏr′ĭ. An Australian river, a tributary of the Darling (q.v.).

MACQUARIE ISLAND. A subantarctic possession of Tasmania, in about lat. 55° S., long. 158° E. (Map: Antarctic Regions, G 7). The main island, 20 miles long by 3 broad, is the summit of a rocky submarine ridge which extends north and south. Its flora is scanty, consisting largely of tussock grass and the Maori cabbage. In the early part of the nineteenth century Macquarie Island was the breeding ground of fur seals, but their unregulated slaughter (35,000 by the first ship) soon exterminated the herds. To-day a fur seal is rarely seen. Birds, however, abound in countless numbers and sea elephants in great herds. The observers of the Mawson (q.v.) expedition report that (1912–13) there were several rookeries of sea elephants, in each of which there were from 400 to 500 cows. The king (second largest of the species) penguins were collected in rookeries, many thousands being seen. The royal penguins nest in countless swarms, and practically hide the ground over areas aggregating 26 acres. As the number annually killed reaches about 150,000 and no decrease is noticed, the entire colonies must approximate half a million. Sheep thrive, and rats are plentiful and troublesome. Macquarie Island is now permanently occupied as a weather and relief station for shipwrecked mariners, 10 persons having escaped from a wreck to remain on the island two years before rescue. Consult Sir Douglas Mawson, *Home of the Blizzard* (2 vols., Philadelphia, 1915).

McQUILLEN, John Hugh (1826–79). An American dentist. He was born in Philadelphia, practiced dentistry as early as 1849, and then studied medicine (M.D., Jefferson Medical College, 1852) and dentistry (D.D.S., Philadelphia College of Dental Surgery, 1853). From 1859 to 1862 he was professor of operative dentistry and dental physiology in the Pennsylvania College of Dental Surgery. In 1863 he founded the Philadelphia Dental College, becoming dean and professor of physiology, which offices he held until his death. He was one of the founders, and for many years president, of the American Dental Association. From 1859 to 1871 he edited and contributed many articles to the *Dental Cosmos*.

MACRAUCHENIA, mā′krą-kē′nĭ-ȧ (Neo-Lat., from Gk. *μακραύχην*, *makrauchēn*, long-necked, from *μακρός*, *makros*, long + *αὐχήν*, *auchēn*, neck). A fossil ungulate mammal of the size of a camel, found in the Pleistocene beds of Argentina. Although of a generalized type, it somewhat resembled the camels in respect of the length and structure of its neck. The muzzle was provided with a short proboscis. The feet were three-toed, with the toes about equal in size.

MACREADY, măk-rē′dĭ, William Charles (1793–1873). A noted English tragedian. He was born in London, March 3, 1793, the son of a provincial theatrical manager, and was educated at Rugby. He first played as Romeo at Birmingham in 1810 under his father's management. He continued with his father for four years; but in 1814 they quarreled and separated. For two years he played at Bath and other provincial towns. In 1816 he decided to try his fortune in London and appeared at Covent Garden as Orestes in *The Distressed Mother*. He met with moderate success and succeeded in winning the applause of Kean; but his progress was slow at first, owing largely to professional jealousies. In 1819 he made a hit in the character of Richard III and afterward adventured on others of Shakespeare's characters with success. In 1826 he made a tour of the United States and visited Paris in 1828. He became lessee of Covent Garden Theatre in 1837, and his management, though brief, was distinguished by the high character of his company and his productions. Later he managed Drury Lane for a time, but without pecuniary success. He visited America a second time in 1843–44; and again in 1848–49. On May 10, 1849, as a result of the jealousy of the American actor Edwin Forrest, a riot occurred at the Astor Place Opera House in New York from which Macready barely escaped with his life. On his return home Macready was engaged at the Haymarket, but his theatrical career was brought to a conclusion with his farewell benefit at Drury Lane, on Feb. 26, 1851. He died at Cheltenham on April 27, 1873. Macready was a fine and impressive player, and a conscientious student of his art. He succeeded best in the graver characters of the drama, having more of the stateliness of Kemble than of the fire of Kean. Consult his *Reminiscences, and Selections from his Diaries and Letters*, edited by Pollock (London and New York, 1875); Lady Pollock, *Macready as I Knew him* (London, 1884); Archer, *William Charles Macready* (ib., 1890); Baker, *English Actors from Shakespeare to Macready* (New York, 1879); Lewes, *On Actors and the Art of Acting* (ib., 1878); Marston, *Our Recent Actors* (London, 1890).

McREYNOLDS, m*a*k-rĕn′oldz, James Clark (1862–). An American lawyer, cabinet officer, and jurist, born at Elkton, Ky. He graduated from Vanderbilt University in 1882 and, in law, from the University of Virginia in 1884. He began the practice of his profession at Nashville, Tenn., where he attained such success and distinction that he was made professor of law at Vanderbilt in 1900. In addition to his professorial duties he continued his practice, particularly in the Federal courts, where his knowledge of corporation law attracted the attention of the Department of Justice. Although a Democrat, he was made Assistant Attorney-General of the United States in 1903 during the administration of President Roosevelt and served until 1907. Thereafter, as special Assistant Attorney-General, he was employed in many of the antitrust cases. His connection with the prosecution of the American Tobacco Company caused him to become widely known, for it was thought that he largely prepared the case for the government. In 1913 he was selected for the post of Attorney-General by President Wilson. This choice was particularly complimentary because of the difficulty of filling adequately the place of Attorney-General Wickersham and because the President announced that it was his especial aim to secure a great lawyer. As Attorney-General, McReynolds was perhaps most widely known as the one to enforce certain of the doctrines of the "new freedom," and, as such, he declared that, while he would insist upon strict compliance of the industrial combinations with the requirements of the law, he would welcome opportunities to adjust such questions without litigation, i.e., to effect a "settlement out of court." His effort was to promote genuine competition in big business. In enforcing the Sherman Anti-Trust Law, he had direction of the dissolution suits against the Union and Southern Pacific Railroad merger, the International Harvester Company, the American Telephone and Telegraph Company (settled out of court), the Reading Company, and the New York, New Haven, and Hartford Railroad. Although sharply criticized by some newspapers regarding the McNab-Caminetti controversy concerning delay in prosecuting a white-slave case, he was also warmly defended and his administration commended. In 1914 he was appointed to succeed Justice Harlan as an associate justice of the United States Supreme Court.

MACRI′NUS, M. Opelius (164–218 A.D.). A Roman Emperor. He was a native of Cæsarea in Mauretania and became pretorian prefect of Rome under Caracalla (q.v.), whom he caused to be assassinated on the expedition against Parthia in 217 A.D. He was at once chosen Emperor by the army, and the Senate confirmed the choice. He fought against the Parthians, neither side gaining a decisive victory, made terms with them, and returned to Antioch. His severe discipline aroused the anger of his soldiers, who were gained over by the relatives of Caracalla, and after a reign of 14 months he was defeated near Antioch and murdered in his flight. He was succeeded by Elagabulus (q.v.). Consult the article "M. Opellius Macrinus," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914).

MACRO′BIUS, Ambrosius Theodosius. A Latin grammarian of the late fourth and the early fifth century. He appears to have been by birth a Greek, but nothing whatever is known of his life. Two of his works remain, entitled *Commentarius ex Cicerone in Somnium Scipionis* and *Conviviorum Saturnaliorum Libri Septem*, commonly known as the *Saturnalia*. The former is the best known and was much read during the Middle Ages; it is a commentary on a dream of Scipio Africanus Minor dealing with the immortality of the soul, which is recorded in Cicero's *De Republica*. The latter is in the form of a dialogue, supposed to have been held at the house of Vettius Prætextatus (325–385 A.D.) during the Saturnalia, and contains many valuable historical, mythological, antiquarian, and critical observations. The author was deeply indebted to Aulus Gellius, both in matters of form and in contents. Books iii–vi deal largely with the criticism of Vergil—in particular with his learning in religious matters, his indebtedness to his Greek and Latin predecessors, especially Homer. Much of value is preserved to us from earlier writers through Macrobius' quotations. Of a third work, *De Differentiis et Societatibus Græci Latinique Verbi*, we possess only extracts made by one Joannes, thought to be Joannes Scotus Erigena, of the ninth century. The grammatical treatise is given in Keil, *Grammatici Latini*, vol. v (Leipzig, 1868). The *editio princeps* of Macrobius appeared at Venice in 1472; of later editions the best are those of Jan (2 vols., Quedlinburg, 1848–52) and Eyssenhardt (Leipzig, 1868, 1893). Consult: Georg Wissowa, *De Macrobii Saturnaliorum Fontibus* (Breslau, 1880); Linke, *Quæstiones de Macrobii Saturnaliorum Fontibus* (ib., 1888); W. S. Teuffel, *Geschichte der römischen Literatur*, vol. iii (6th ed., Leipzig, 1913).

MACROCOSM. See Microcosm and Macrocosm.

MACROCYSTIS, măk′rô-sĭs′tĭs. A genus of brown algæ whose species are commonly called giant kelps. They are particularly conspicuous along the Pacific coast of the United States. The stipe is firmly anchored by a holdfast, and the long ropelike stems float on the surface, bearing numerous leaflike blades. These floating stems are said to attain sometimes a length of 600 to 900 feet.

MACROGLOSSIA, măk′rô-glŏs′ĭ-ȧ. See Tongue.

MACROPOMA, măk′rȯ-pō′mȧ (Neo-Lat., from Gk. *μακρός, makros*, long + *πῶμα, pōma*, cover, lid). A fossil fish of the order Crossopterygii, found preserved in fine condition in the chalk beds of the English Cretaceous formations. The body was about 18 inches in length, of stocky form, and was covered with overlapping ganoid scales. The head was protected by rather heavy bones. The fins are simply lobate and consist of anterior and posterior dorsal, an anal, a pair each of pectoral and pelvic, and a broad caudal fin. The air bladder was ossified and is often found preserved in the better specimens. See GANOIDEI.

MAC′ROSPORAN′GIUM. An almost obsolete name for megasporangium (q.v.).

MAC′ROSPORE. An almost obsolete name for megaspore (q.v.).

MAC′ROSPOR′OPHYLL. An older and almost obsolete name for megasporophyll (q.v.).

MACROZA′MIA (Neo-Lat., from Gk. *μακρός, makros*, large + *ζαμία, zamia*, loss; so called because of the sterile appearance of the male fructification). A genus of Australian cycads, including about 14 species. The name means 'large *Zamia*,' a genus characteristic of the Occidental tropics. The stem ranges from tuberous and subterranean to more or less columnar and aërial. The fernlike leaves, as in other cycads, occur in a conspicuous crown or rosette at the summit of the stem.

MACRU′RA. See CRUSTACEA.

MACRURIDÆ. See MACRURUS.

MACRU′RUS (Neo-Lat., from Gk. *μακρός, makros*, long + *οὐρά, oura*, tail). The type genus of a family of fishes (Macruridæ) which are closely allied to the cods, seeming degenerate representatives of the stock and differing chiefly in the elongate and degenerate condition of the posterior part of the body, which tapers to the thin, much compressed tail. (See Plate of CODFISH AND ALLIES.) All are pelagic, and most of them inhabit the deeps and have the characteristics of deep-sea fishes. *Bathygadus* is another prominent genus. Consult Goode and Bean, *Oceanic Ichthyology* (Washington, 1896). See DEEP-SEA EXPLORATION.

McTAGGART, JOHN MCTAGGART ELLIS (1866–). An English philosopher, educated at Clifton College and at Trinity College, Cambridge, where he became a fellow in 1891 and lecturer in 1897. He was made a fellow of the British Academy and received an honorary LL.D. from St. Andrews. He published: *Studies in the Hegelian Dialectic* (1896); *Studies in Hegelian Cosmology* (1901); *Some Dogmas of Religion* (1906); *A Commentary on Hegel's Logic* (1910).

McTYEIRE, măk-târ′, HOLLAND NIMMONS (1824–89). An American bishop of the Methodist Episcopal Church South. He was born in Barnwell District, S. C., graduated from Randolph-Macon College, Va., in 1845, and entered the ministry, joining the Virginia conference. Later he became a member of the Alabama conference, and finally of the Louisiana conference. He was editor of the New Orleans *Christian Advocate* from 1851 to 1858, and then became editor of the *Christian Advocate* of Nashville, Tenn. The misfortunes of the Civil War having interrupted the publication of this paper, McTyeire was compelled to return to the pastorate and was stationed at Montgomery, Ala., during the war. He was a member of the General Conferences of 1854 and 1858; was one of the founders of Vanderbilt University; and, elected Bishop in 1866, was senior Bishop at the time of his death. He was author of *A Catechism of Bible History* (1869); *A Manual of Discipline of the Methodist Episcopal Church South* (1876); *A Catechism on Church Government, with Special Reference to the Methodist Episcopal Church South* (1878); *A History of Methodism* (1885); *Passing through the Gates, and Other Sermons* (1889); *Rules of Order for Deliberative Assemblies* (n. d.). Consult O. P. Fitzgerald, *Holland N. McTyeire* (Nashville, 1896).

MACÚ, mȧ-ko͞o′. One of the lowest tribes of the Amazon region, with no fixed residence, but wandering nearly the whole length of the Rio Negro, principally to the west of it, in northwestern Brazil. They are naked and without houses, but stitch a few palm leaves together to serve as a shelter at night in case of rain. They live entirely by hunting and fishing, using poisoned arrows, and are hostile to other tribes. Their hair is wavy and almost curly. They must not be confounded with the Maca (q.v.), or with the Maco of the Upper Orinoco. Consult Theodor Koch-Grünberg, in *Anthropos*, vol. i (Salzburg, 1906), and id., *Zwei Jahre unter den Indianern* (Berlin, 1909–10).

MAC′ULA (Lat., spot). A macule, spot, or stain, of limited area and circumscribed, without elevation or depression of surface. Maculæ is a term used in dermatology of not only macular diseases, but also some vesicular and papular affections, including nævus, ephelis, spilus, moles, etc.

MacVEAGH, măk-vā′, FRANKLIN (1837–). An American business man and cabinet officer, born near Phœnixville, Chester Co., Pa. He was educated by private tutors, at Freeland Seminary (now Ursinus College), and at Yale (A.B., 1862). He then entered Columbia Law School, from which he graduated in 1864. For a year he practiced law with his brother, Wayne MacVeagh, in Philadelphia; but finding his health failing he moved to Chicago, where he entered the wholesale grocery business with the firm of Whittaker and Harmon. Although the firm's property was destroyed by the great fire of 1871, MacVeagh was a tireless leader in the relief work and was warmly praised. Reorganized under the name of Franklin MacVeagh & Co., the corporation became one of the largest and most successful of its kind in the United States. MacVeagh also became interested in banking. In 1874 he may perhaps be said to have entered politics—as head of the Citizens' Association, an organization which investigated municipal conditions and the government and made recommendations regarding the elimination of certain grafting practices. In municipal matters MacVeagh acted with the Republican party, but later, with respect to national politics, he supported the candidacy of Cleveland in each of his campaigns. In 1894 he was nominated by the Democratic State Convention as candidate for United States Senator, but was defeated by the incumbent, Cullom. In 1896 he returned to the Republican party on the silver question. After the election of Taft in 1908 he was offered, and accepted, the post of Secretary of the Treasury, and he served throughout the administration. One of his first acts as Secretary was to order an inquiry to ascertain where economies might be effected. He was a promoter of the National Civic Federation, and was known as a man of wide attainments, being a member of various scientific and learned societies. Yale gave him the degree of LL.D. in 1912.

MacVEAGH, WAYNE (1833–1917). An American lawyer, diplomat, and cabinet officer, a brother of Franklin MacVeagh. He was born near Phœnixville, Chester Co., Pa., graduated at Yale in 1853, and after studying in the law office of James J. Lewis, of West Chester, was admitted to the Pennsylvania bar in 1856. He was a captain of infantry in 1862 and of cavalry in 1863, when invasions of Pennsylvania were threatened. From 1859 to 1864 he was district attorney of Chester County. He became prominent early as a Republican leader, fighting strongly against the machine in control, and in 1863 was chosen chairman of the State Committee. In 1870–71 he was United States Minister to Turkey, and in the latter year also led the fight in Pennsylvania Republican politics against Simon Cameron, his father-in-law, although remaining friendly in social associations. In 1877 he was chairman of the "MacVeagh Commission," sent unofficially by President Hayes to secure an amicable adjustment of the political differences in Louisiana. In March, 1881, he entered the cabinet of President Garfield as Attorney-General, but resigned on the accession of President Arthur and resumed his law practice. Under President Cleveland, whom he had supported in the campaign of 1892, MacVeagh was Ambassador to Italy. In 1896 he returned to the support of Republican candidates. Distinguished as a lawyer, in 1903 he was chief counsel for the United States in the Venezuela arbitration before The Hague Tribunal, and for many years he served as counsel for the Pennsylvania Railroad Company. He contributed to periodicals articles on international peace.

MacWHIRTER, măk-hwẽr′tẽr, JOHN (1839–1911). A Scottish landscape painter, born near Edinburgh. At 13 he ran away from home and became a pupil of Lander and Ballantyne in the art school of the Board of Manufacturers, Edinburgh. He exhibited at the Scottish Academy when only 15, and later traveled extensively in Europe and America, everywhere painting nature's gentler moods, and particularly excelling in masterful rendering of trees. His early work possesses charming color and graceful design, but his later paintings are often weak both in technique and sentiment. Among his finest landscapes are "The Lady of the Woods" (1876), "The Three Graces" (1878), "The Sleep that is among the Lonely Hills" (1896), "A Winter Fairy" (1898), "Over the Sea from Skye" (1900). He is represented in the Tate Gallery, London, and in the Liverpool and Birmingham galleries. In 1869 he took up his residence in London, and in 1877 made a visit to the United States, where he executed some notable studies of California scenery. He was elected a Royal Academician in 1894. In 1901 appeared his *Landscape Painting in Watercolors*. Consult W. M. Sinclair, "John McWhirter, His Life and Work," in *Art Annual* (London, 1903).

MACY, mā′sĭ, JESSE (1842–). An American historian, born in Henry Co., Ind. He graduated at Iowa (now Grinnell) College in 1870; the next year was appointed principal of the academy of the college, and in the college itself became professor of constitutional history and political science in 1885. Made professor emeritus in 1912, during the following year he visited French provincial universities as lecturer on the Harvard Foundation. Macy published: *Civil Government in Iowa* (1881); *Institutional Beginnings in a Western State* (1883); *Our Government* (1886); *The English Constitution* (1897); *Political Parties in the United States, 1846–61* (1900); *Party Organization and Machinery* (1904; new ed., 1912); *Political Science* (1913).

MADÁCH, mŏ′däch, IMRE (1823–64). An Hungarian poet, born of a noble family in the county of Nógrád. He studied law at Pest and became notary for his district. In 1861 he published a dramatic poem called *Az ember tragédiája* (The Tragedy of Man), which was considered the best of its kind that had appeared in Hungary. There are several German translations. Selections in English have appeared in vol. xvi of *The Library of the World's Best Literature*. His collected works were published by Paul Gyulai in 1880.

MAD′AGAS′CAR (corrupted from *Magadaxo;* formerly called by the natives *Izao rehetra Izao,* this whole, i.e., world, and *Ny anivon ny riaku,* [land] in the midst of the flood). A French colony, the sixth largest island in the world, being surpassed in area only by Australia, Greenland, New Guinea, Borneo, and Baffin Land. It is situated in the Indian Ocean off the southeast coast of Africa, from which it is separated by Mozambique Channel. It lies between lat. 11° 58′ and 25° 35′ S. and long. 43° 19′ and 50° 27′ E. It is 980 miles long and 358 miles in its greatest width, with an area (including the few adjacent islets) of 228,000 square miles (estimated), or about two and one-half times that of Great Britain (Map: Africa, J 6).

Topography and Geology. Madagascar may be divided into two distinct regions. The central and the eastern parts of the island, or more than half of it, are very mountainous and are formed of primitive rocks of igneous origin, except for a narrow fringe of sedimentary rocks along the coast. Gneiss, and particularly granitoid gneiss, predominates; there are also many granite dykes and, here and there, basalts, the cones of ancient volcanoes, magnetite and other iron ores, and numerous hot springs. The gneiss, decomposed to great depths, forms the reddish, clayey soil that covers most of these highlands. The volcanic centres (now extinct) of this region are Mount Ankaratra in the central region, the culminating summit of the island (nearly 9000 feet high), Mount Amber near the north end of the island, and Ivohitsombe near the southeast coast, north of Fort Dauphin. These highlands, the primitive land mass, rise from 3000 to 6000 feet above the sea.

The western and southern regions and a considerable district in the north are comparatively low, not much over 600 feet above sea level, and are built up of sedimentary rocks of Jurassic and Cretaceous periods, with some Eocene and Quaternary beds. Here also are many volcanic cones that have pierced through the sedimentary fossiliferous beds. The lowlands, broken by some ranges of hills extending north and south, rise gently to the central highlands, and the rivers have excavated numerous valleys, so that the west of the island is, for the most part, a deeply dissected plain. The coasts are in the main comparatively straight, with no deep indentations. The northwest coast, however, is broken up by great inlets, some of them landlocked, so that Mojanga and a few other bays are among the largest and finest of natural harbors. Elsewhere the island is poorly supplied with good ports for shipping.

Hydrography. Naturally, the rivers that are most important in an economic sense flow down the western slope across the plains to Mozambique Channel. The largest of these western rivers are the Betsiboka, the Tsiribihina, the Mangoka, and the Onilahy, all navigable for some distance by small vessels, and the Betsiboka for about 100 miles. The eastern rivers are torrential streams making their short course to the sea through gloomy but magnificent gorges under the shade of the densest forest growths. The largest of these rivers is the Mangoro. The only lake of importance is the Alaotra, among the mountains of the northeast. South of Tamatave, on the east coast, is a series of lagoons which the French have connected by 30 miles of canals, making an inland waterway about 100 miles long.

Climate. Owing to its geographical position and the considerable elevation of a large part of the island, Madagascar has both the temperate and tropical climates. The centre, with a mean elevation of about 4000 feet, has a temperate climate with a dry and wet season and a temperature rarely rising above 72° F. Here white men can best live and labor. The east has a warm and humid climate with rain nearly every day in the year, the precipitation at Tamatave, e.g., being over 90 inches in a year. The hot west coast has a dry season under the rain shadow of the mountains during the prevalence of the southeast trades and a wet season under the doldrums from November to April. All the coast regions are very unhealthful. The south of the island is marked by long periods of drought. Sometimes not a drop of rain falls in a year. The weather service has 42 stations.

Flora. The flora is very rich and varied; three-fourths of the species are endemic and there are almost 4000 indigenous species; but the rainfall dictates four botanical areas, in the east, west, centre, and south. The east, receiving the larger rainfall, has extensive forests of tropical timber, including many valuable species. A large part of the centre, on the contrary, being comparatively dry, is almost destitute of vegetation. It is only around the villages and along the rivers that trees and cultivated lands are found. The reason is that the moisture-laden winds from the Indian Ocean part with their water vapor on the eastern slopes of the mountains and west of the crests there is much smaller rainfall. In the west are found large expanses of prairies adapted for extensive cattle raising, with here and there clumps of timber and isolated trees. A belt of forest parallels the west coast at some distance from it, but it is by no means so luxuriant as the eastern forests. Cacti and euphorbias are found in the dry south, where the botanical aspects of the country resemble those of the dry plateaus of Mexico.

Fauna. See MALAGASY SUBREGION.

Progress of Geographical Knowledge. When General Gallieni conquered the island in 1896 he said the first duty of the French was to study their new possession. The progress of field surveys and exploration under his direction was remarkable. The military detachments that visited all parts of the island in the work of pacification were accompanied by topographers, whose map results have been compiled in a large map on a scale of about 8 miles to an inch. Many parts of the island are now mapped on a scale of about 1½ miles to an inch, and the capital and its surroundings on a scale of about ⅝ mile to an inch. All mountain ranges, streams, town roads, trails, mission stations, and much other information are shown on the maps.

Resources. Cattle raising is important; notwithstanding primitive native methods, the natural conditions are so favorable that the herds show great increase from year to year, as evidenced by the annual live-stock census (taken on account of the tax levied), which showed 2,342,792 cattle in 1904, 3,812,671 in 1908, 4,492,131 in 1910, and 5,320,200 in 1913. These figures are exclusive of calves and of the great herds running wild in the western regions. Rice is the principal cultivated crop, and extended in 1914 over 396,130 hectares. From 1901 imports of this staple have decreased annually, until in 1912 there was an export of 7420 tons, valued at 1,675,773 francs. In 1901 the import was valued as 5,640,636 francs. Other agricultural products are manioc, corn, peas, vanilla, coffee, etc. The forests yield ebony, rubber, and wax. From the mines come gold, silver, iron, copper, lead, and zinc.

Commerce. In the over-sea trade, the imports for consumption in 1912 were valued as 50,034,848 francs (40,470,813 francs in 1900), detailed in part as follows: cotton textiles, 22,768,330 francs; metal manufacturers, 4,759,193; metals, 1,703,119; wines, 1,950,643; spirits, 995,391. The total exports of domestic products in 1912 were valued at 59,844,294 francs (10,623,869 in 1900): raw hides, 10,752,572 francs; raw gold, 5,989,175; rubber, 5,181,431; vanilla, 3,941,521; raffia, 3,787,936; legumes, 2,807,575; wax, 1,696,760; cattle, 1,008,685; ebony, 425,000. In the total trade France contributed imports valued as 47,541,971 francs and received exports valued as 49,417,553 francs. There were entered at the ports (the chief ports are Tamatave, Majunga, and Diego-Suarez, qq.v.) in the 1912 foreign trade 10,937 vessels, of 1,756,764 aggregate tons.

Communications. A railway completed early in 1913 unites the capital with Tamatave, a distance of 369 kilometers. A law passed Dec. 31, 1912, authorized the construction of a line from the capital to Antsirabe. The existence of roads is contemporaneous with the French occupation of the island. At great cost and in the face of extraordinary obstacles the department of public works has established the following main routes, traversed by regular automobile service: the Eastern, Western, and Southern, the Antananarivo-Miarinarivo, the Fianarantsoa-Mananjary, and the Mangoro-Lake Alaotra routes.

Administration. The colony of Madagascar is divided for purposes of administration into 21 provinces, the commune of Sainte-Marie, and the autonomous districts of Ankazobe and Ambilobe, administered by residents and vice residents under the direction of a governor-general. By the decree of March 31, 1914, the Comoro Islands dependency was created a province of Madagascar. The first resident general arrived at Antananarivo Jan. 16, 1896, and the law declaring Madagascar and its dependencies a French colony was passed Aug. 6, 1896. The decree of July 31, 1897, created General Gallieni, resident general from Sept. 28, 1896, governor-general of Madagascar and its dependencies.

Slavery was abolished by the decree of Sept. 27, 1896, and the system of enforced native labor has since been abolished. The troops stationed at Madagascar include two battalions of colonial infantry, a regiment of colonial artillery, three regiments of Malagasy *tirailleurs*, one battalion of Senegalese *tirailleurs*, and two companies of noncombatants. The budget for 1911 balanced at 31,153,000 francs; the debt stood, Jan. 1, 1912, at 98,220,000 francs. The government maintained, at the end of 1913, 609 elementary native schools in which both the French language and the Hova dialect were taught, eight regional continuation schools, four special and two high schools. There are primary and secondary schools for Europeans. There are courts of justice and of appeal for Europeans, and native tribunals for aboriginals.

Population. The population according to the census of 1911 was 3,104,881; with dependencies, 3,154,000. As calculated Jan. 1, 1914, the inhabitants of the island numbered 3,253,581 (3,351,481 with dependencies), as follows: 14,918 whites, 12,905 Asiatics, 3,225,758 aboriginals. Antananarivo (Tananarive), the capital, has about 72,000 inhabitants.

Ethnology. The generic term for the natives of Madagascar is Malagasy. Of their three principal tribes, the Hovas are Indonesians, more or less mixed with Malay. They are supposed to be the last wave of the Malay migration, coming about eight centuries ago. They have straight black hair and olive-yellow skin; their eyes are sometimes narrow; their stature is short, their noses prominent and sharp; their head is globular. Agriculture, cattle raising, and trading are their occupations. Their principal food is rice, which is cultivated with the aid of artificial irrigation, recalling the terrace system of the Philippines. Many other customs and arts pointing to their ancestral home are preserved, as the square pile house, bellows, outrigger canoe, musical instruments, dress, taboo, infanticide, ordeal, burial, and the like. The Hovas were until recently the ruling people on the island and were gradually subjecting the other tribes, to which they are much superior in culture. They were divided into nobles, freemen, and slaves. In recent years, however, these class distinctions became weaker and the royal and slave classes were finally abolished by the French. They are nominally Protestants in religion. In practice pagan taboos and a system of divination with 16 as the mystic number play a great part. The latter is almost certainly derived from Arabic geomancy. The principal tribes of the Hovas are the Voromahevy, Tsimianboholahy, Tsinahafoty, Mandiavato, Marovatana, and others. The Betsileos living to the south should also be placed with the Hovas.

The Betsimisarakas are less pure than the Hovas and are dolichocephalic; they are below the average height and have curly or almost smooth hair and light chestnut complexion. They are rather backward in culture and show influences due to the Arabs who settled in Madagascar about five centuries ago. The principal tribes are the Antambahoaka, Antaimoro, Antaifasina, Antaisaka, Antaisara, Antanosi, Tanala, and Sihanaka. They were conquered by the Hovas early in the nineteenth century.

The Sakalavas are dark, long-headed, and of high stature; their hair is frizzly, their lips thick, and their noses flat. Most strongly of all the Madagascar tribes they show the negro element. The best-known tribes are the Menabe, Milaka, Ronondra, and Mahafali.

History. Madagascar appears on Arabian charts of the twelfth century and it is probable that Arab traders visited the country as early as the eighth or ninth century. Marco Polo used the name *Madeigascar*, but apparently applied it to what is now Mozambique, on the mainland of Africa. The discovery of the island by the Portuguese occurred in 1500, when, according to Grandidier and Reclus, Diego Diaz sighted the land and named it São Lourenço. Attempts at settlement made before 1540 by the Dutch, English, and Portuguese failed, but in the seventeenth century the French set up a claim to Madagascar, or Dauphiné, as they called it, and in 1642 Louis XIV granted it to the Compagnie de l'Orient. Stations were established at Sainte-Marie and Fort Dauphin, but the rule of the French was so cruel that the natives rose in 1672 and massacred them. France regained Sainte-Marie in 1750, lost it to Great Britain during the Napoleonic wars (1814), and reoccupied it after 1815, together with Tamatave, Fort Dauphin, and Sainte-Luce. French influence, however, made little progress owing to the rise of the powerful monarchy of the Hovas, a people of the central plateau, who, under the leadership of Andriananimpoina, had subjugated the greater part of the island. During the reign of Radama I (1810–28) the British gained the ascendancy. English officers drilled the Hova troops and English missionaries introduced schools and the Christian religion. Under Queen Rànavàlona I (1829–61) a strong reaction from European ideas occurred. Reforms were abolished, the missionaries were persecuted, and trade relations with England were broken off. Christianity was declared illegal in 1835. An unsuccessful attack on Tamatave by the English and French in 1845 led to a general massacre of Christian converts (Malagasy). After 1853, however, the Europeans regained an entrance into the capital, Antananarivo, through the influence of Prince Rakoto, heir to the throne. As Radama II (1861) Rakoto showed himself friendly to the French, and undertook to restore the reforms of Radama I. He was murdered by the conservative faction at court. Though Queen Rànavàlona II adopted Christianity in 1869, the Hova government remained jealous of European aggression and took measures to prevent the foreign acquisition of land in the island. In 1883 the invasion of French territory and the plundering of French citizens led to the bombardment of Tamatave. After two years' desultory fighting Madagascar, by treaty, became virtually a protectorate of France, though it retained its nominal independence. Renewed hostility on the part of the Hovas was followed in 1895 by the dispatch of a French expedition under Duchesne, which occupied Antananarivo and forced Queen Rànavàlona III to confirm the Treaty of 1885. In 1896 Madagascar was declared a colony of France, though the native government was retained, and a proclamation was issued abolishing slavery. The same year the outbreak of a rebellion in which the court was found concerned led to the deposition of the Queen and the institution of a military government. The former Queen was exiled to Réunion, and afterward to Algeria. In 1907 almost all the native churches on the island were abolished. Governor Albert Picquié (appointed 1910) has paid particular attention to internal improvements, and the resources of the country are rapidly being opened up.

Bibliography. Three comprehensive works are: Grandidier, *Histoire physique, naturelle et politique de Madagascar* (to be in 50 vols., Paris, 1876 et seq.); James Sibree, *The Great African Island* (London, 1880); S. P. Oliver, *Madagascar* (ib., 1886), which has an excellent bibliography. Mission work and manners and customs are treated in James Sibree, *Madagascar and its People* (ib., 1870); La Vaissière, *Histoire de Madagascar, ses habitants et ses missionnaires* (Paris, 1884); and an account of Roman Catholic missions is Colin and Sua, *Madagascar et la mission catholique* (ib., 1895). For the ethnology: William Ellis, *Three Visits to Madagascar* (London, 1858); Arnold van Gennep, *Tabou et totemism à Madagascar, étude descriptive et théorique* (Paris, 1904); Haupt Graf zu Pappenheim, *Madagascar* (Berlin, 1906). For the fauna: Pollen and Van Dam, *Recherches sur le faune de Madagascar* (5 vols., Leyden, 1868); James Sibree, *A Naturalist in Madagascar* (Philadelphia, 1914). For the people: Lyons McLeod, *Madagascar and its People* (London, 1865); Oliver, *Madagascar and the Malagasy* (ib., 1866); Carol, *Chez les Hova, au pays rouge* (Paris, 1898). For Madagascar as a colony and for the French occupation: Leroy, *Les français à Madagascar* (Paris, 1803); Gaston Routier, *Les droits de France sur Madagascar* (ib., 1895); F. C. Maude, *Five Years in Madagascar* (London, 1895); Brunet, *La France à Madagascar* (Paris, 1895); Olivier, *Ce qu'il faut connaître de Madagascar* (ib., 1895); Dawson, *Madagascar: Its Capabilities and Resources* (London, 1895); Knight, *Madagascar in War Time* (ib., 1896); Hanotaux, *L'Affaire de Madagascar* (Paris, 1896); Burleigh, *Two Campaigns: Madagascar and Ashantee* (London, 1896); *Rapport sur l'expédition de Madagascar* (Paris, 1897); *Guide de l'immigrant à Madagascar* (3 vols., ib., 1899); Mignard, *Etude sur l'établissement de la domination française à Madagascar* (ib., 1900); J. S. Gallieni, *La pacification de Madagascar* (ib., 1900); id., *Madagascar de 1896 à 1905* (Antananarivo, 1905); A. You, *Madagascar: histoire, organisation, colonisation* (Paris, 1905); W. M. Marcuse, *Through Western Madagascar* (London, 1914). Other works are: James Sibree, *A Madagascar Bibliography* (London, 1885); Paisant, *Madagascar* (Paris, 1896); James Sibree, *Madagascar before the Conquest* (London, 1896); Johnston, *The Colonization of Africa* (Cambridge, 1899); Foucart, *Madagascar: commerce, colonisation* (Paris, 1899); W. H. Hunt, "Madagascar," in *American Geographical Society, Journal*, vol. xxxii (New York, 1900); T. T. Matthews, *Thirty Years in Madagascar* (ib., 1904). *Bulletin Economique —Revue de Madagascar* is a periodical published at Antananarivo.

MADAGASCAR (in zoögeography). See Malagasy Subregion.

MADAGASCAR CAT. A lemur (q.v.).

MADAMA (mä′dȧ-mä) **BUTTERFLY.** An opera by Puccini (q.v.), first produced in Milan, Feb. 17, 1904; in the United States, Nov. 12, 1906 (New York).

MADAME BOVARY, mȧ′dȧm′ bō′vȧ′rē′. The most notable romance of Gustave Flaubert.

MADAME CHRYSANTHÈME, krē′zäN′tĕm′. A romance by Pierre Loti (1887).

MADAME SANS-GÊNE, säN′zhân′. A play and an opera. The play, by Sardou and Moreau, was first produced at the Vaudeville, Paris, in 1893. The personages are Napoleon I and the homely characters whom he made his courtiers. The opera, by Umberto Giordano (q.v.), was first produced at the Metropolitan Opera House, New York, Jan. 25, 1915.

MAD′AN, Falconer (1851–). An English author and librarian, born at Cam, Gloucestershire. He was educated at Marlborough (1864–70) and at Brazenose College, Oxford, where he was scholar from 1870 to 1875 and fellow from 1876 to 1880. From 1880 to 1912 he was sublibrarian of the Bodleian Library and thereafter librarian, and over a long period (1889–1913) he held the university lectureship in paleography. His writings are chiefly included in: *Books in Manuscript* (1893); *Summary Catalogue of Bodleian MSS.*, vols. iii–vi (1895–1906); *Oxford Books, 1468–1650* (2 vols., 1895–1911); *The Gresleys of Drakelowe* (1899); *Chart of Oxford Printing* (1903–04); *Account of the Oxford University Press* (1908).

MAD′AN, Martin (1726–90). An English writer. His father, a colonel, was a member of Parliament and his mother was an aunt of the poet Cowper. From Westminster School he passed to Christ Church, Oxford, where he graduated B.A. in 1746. In 1748 he was called to the bar. Impressed by Wesley's preaching, he gave up his profession, and, with the aid of Lady Huntington, who had turned Methodist, he was admitted to holy orders. He was appointed chaplain to the Lock Hospital in London, where he became widely known. In 1780 he published *Thelyphthora*, a book in which it was argued that polygamy is in accord with the Mosaic law and with Christianity rightly understood. The work created a sensation. Madan resigned his chaplaincy and retired to Epsom, where he died May 2, 1790. Besides the famous *Thelyphthora*, Madan published a score of other books and pamphlets, including several on polygamy, translations of Juvenal and Perseus (both in one volume, 1789), and a collection of psalms and hymns.

MAD ANTHONY. A nickname given to Major General Anthony Wayne because of his reckless daring in the American Revolution.

MAD APPLE. See Sodom, Apple of.

MAD CAVALIER. A name given to Prince Rupert of Bavaria, nephew of Charles I of England.

MADDALONI, mäd′dȧ-lō′nē. A city and railway centre in the Province of Caserta, Italy, 4 miles southeast of Caserta. It is situated in a finely irrigated and fertile district. The palace of the Caraffa family and the church of San Michele stand on a height above the city. In the vicinity is the famous Caroline aqueduct, which supplies Caserta with water. The principal industries are quarrying, weaving, and pottery manufacture. Pop. (commune), 1901, 20,682; 1911, 19,784.

MAD′DEN, Sir Frederick (1801–73). An English antiquary, born in Portsmouth. He entered the service of the British Museum in 1826 as a cataloguer, two years later was made assistant keeper of the department of manuscripts, and in 1837 keeper. In 1834 he was gazetted one of the gentlemen of the privy chamber. The foremost paleographer of his time, he continued to hold his post in the British Museum until 1866, when he retired, devoting the remainder of his life to antiquarian and literary study. He edited the metrical romance of *Havelok the Dane* (1833); *Layamon's Brut, or Chronicle of Britain* (1847); Wiclif's *Bible* (1850); Matthew Paris's *Historia Anglorum* (1866–69).

MADDEN, Richard Robert (1798–1886). A British traveler and author, born in Dublin. In 1833 he was sent to Jamaica as one of the special magistrates to administer the Emancipation Act; in 1836 was appointed a judge in the Mixed Court at Havana; and in 1841 served as a member of the inquiry commission to report on slave-trade conditions on the African west coast. From 1843 to 1846 he was Lisbon correspondent of the London *Morning Chronicle*, in 1847 was Colonial Secretary of Western Australia, and from 1850 to 1880 was secretary of the Loan Fund Board of Dublin Castle. A physician by profession, trained in Paris, Naples, and London, in 1855 he was made a fellow of the Royal College of Surgeons, London. His chief works are *The United Irishmen: Their Lives and Times* (1843–46; new ed., 12 vols., New York, 1910) and *The History of Irish Periodical Literature* (1867).

MAD′DER (AS. *mædere, mæddre*, Icel. *maþra*, madder), *Rubia*. A genus of plants of the natural order Rubiaceæ, very nearly allied to the genus *Galium* or bedstraw (q.v.), and differing from it chiefly in having a juicy fruit resembling two small berries growing together. The species are found in the tropical and warmer temperate parts, both of the Old and the New World, and are important for the coloring matter of their roots. The most important is the common madder or dyer's madder (*Rubia tinctorum*), a native, probably, of the south of Europe as well as of Asia and now cultivated in most European countries and also in the East Indies, China, etc. It is a perennial, with weak stems and whorls of 4–6 elliptic or lanceolate glossy leaves, the stem and leaves rough with sharp prickles; small greenish-yellow flowers, and black fruit. The Turkish madder (*Lizari* or *Alizari*) was probably the earliest in use, but the limited amount imported to the United States is principally from Holland. In the Levant the plants are plucked when five or six years old, but in Europe they are allowed to grow only two or three years. The best quality, known as *crop madder*, is that which is freed from the brown outer crust before grinding. *Mull madder*, the most impure variety, is obtained by grinding rootlets, the woody parts of the root, brown outer crust, and all. From the madder roots are prepared, by fermentation and filtration of the separated dye colors, the commercial products known as garancine, flowers of madder, commercial alizarin, and madder extracts. Madder extracts consist of mixtures of the two coloring mattes of madder, alizarin and purpurin. The importance of madder and madder preparations has almost entirely disappeared with the development of the artificial manufacture of alizarin. Consult S. P. Sadtler, *Industrial Organic Chemistry* (4th ed., Philadelphia, 1912), and Sir T. E. Thorpe, *Dictionary of Applied Chemistry* (rev. and enl. ed., London, 1912). See Alizarin.

MADDER, Indian. See Chay Root.

MADDER FAMILY. A popular name for a family of plants. See Rubiaceæ.

MADDER LAKE. See Paints; Lakes.

MAD′DERN, Minnie. An American actress. See Fiske, Minnie Maddern.

MADEIRA, mȧ-dē′rȧ, *Portug. pron.* mȧ-dā′rȧ. The chief of the Madeira Islands, in the Atlantic Ocean, about 400 miles west of Morocco, just south of the parallel of lat. 33° N. (Map: Portugal, E 5). It is about 38 miles long and 12 miles broad, and has an area of about 300 square miles. Its surface is rough and diversified with high peaks and deep valleys; it is traversed by a ridge of mountains, attaining in Pico Ruivo an altitude of 6568 feet above the sea. Their average height is estimated at 4000 feet, and the more elevated peaks are often covered with snow. Madeira is of volcanic origin, and although it has no active volcanoes at present, there are numerous traces of lava streams. The scenery is magnificent, the deep valley known as the Curral das Freiras being especially picturesque. The coasts are generally high, with precipitous, rocky cliffs, reaching in Cabo Girao a sheer height of 1934 feet. The climate of Madeira is remarkable for its uniformity and salubrity, and the island is regarded as one of the best of health resorts and much recommended to sufferers from chest complaints. The average temperature at the coast for the year is about 68° F., that of the coldest month being about 60° F., and that of the warmest 73° F. The island is, however, exposed to the deadly leste (east wind), or hot sand storm from the Sahara Desert. The absence of rain during the summer, under the sway of the horse latitudes, necessitates a complete system of irrigation. The water is stored up during the rainy season on the hills and distributed in the summer by means of channels. The vegetation of Madeira is one of the richest and includes more than 80 species of plants peculiar to the island. In addition to European grains and fruits, there is an abundance of bananas, figs, grapes, apricots, custard apples, mangoes, oranges, pineapples, and citrons. The fauna is less varied; there are no indigenous mammals and no snakes, though lizards and turtles are found. Birds, however, are very numerous and are characterized by a remarkably bright plumage. The most common species is the wild canary. The wine industry, which was introduced from Crete in the sixteenth century and for which the island is famous, is still very extensive, the annual export amounting to about 700,000 gallons, although it has considerably declined since the grape disease of 1851–52. Besides wine the island produces sugar, tobacco, and coffee. Among the other industries may be mentioned lace weaving, wood carving, and the manufacture of cigars. In 1900 the district of Funchal had a population of 150,574, of whom 148,263 were in Madeira; in 1911 (census of December 1), 169,783, of whom 167,601 in Madeira. Males, 73,637; females, 87,964; illiterate, 67,058 males, 71,596 females; able to read, 12,579 males, 16,368 females. The people are of Portuguese descent, with some Moorish and negro intermixture. The population of Funchal (q.v.), the capital of the district, was 20,844 in 1900 and 24,687 in 1911. The dominant religion is Roman Catholic, but the Church of England and the Free church of Scotland are also represented. The island is connected by steamship lines with the United States, Great Britain, France, Belgium, Portugal, and the not distant Canary Islands. Madeira is supposed to have been known to the Phœnicians in ancient times. It was rediscovered by the Portuguese explorer João Gonçalvez Zarco in 1419 and colonized about 30 years later. In 1580 the island fell into the hands of the Spaniards, but was restored to the Portuguese in 1640. In 1801 and from 1807 to 1814 Madeira was occupied by the British, but since then it has remained in the possession of Portugal. For bibliography, see Madeira Islands.

MADEIRA. The principal tributary of the Amazon (Map: Brazil, E 5). It is formed on the boundary between Bolivia and Brazil by the union of the Mamoré and the Beni and flows northeastward with numerous windings, forming in a part of its course the boundary between the Brazilian states of Matto Grosso and Amazonas. It enters the Amazon about 50 miles below the mouth of the Rio Negro after a course of about 900 miles from the confluence of its head streams, and about 2200 miles from the remotest source of the Mamoré. For the first 200 miles below the junction the Madeira flows through rocky gorges in a series of falls and rapids ending in the Falls of São Antonio, 715 miles from its mouth. Below this point it is a majestic river nearly a mile wide, and navigable for ocean steamers during nine months of the year, and for steamers drawing 8 feet at all seasons. A railroad past the falls, from São Antonio to the union of the Mamoré and Guaporé, is in the course of construction and will aid in the development of the State of Matto Grosso and parts of Bolivia. The vast forest region through which the river flows is almost wholly undeveloped, to a large extent unexplored, and almost uninhabited, save by tribes of Indians and by rubber gatherers, who have made a number of settlements along the banks, this being one of the chief rubber-producing regions in the world. The name Madeira, which means 'timber,' was given to the river on account of the great quantities of driftwood sent down by the current. The Madeira was explored, and its principal tributary, the Rio Teodoro (q.v.), formerly the Rio Dúvida (River of Doubt), was put on the map by the Roosevelt-Rondon scientific expedition in 1914.

MADEIRA ISLANDS. A group of islands in the Atlantic Ocean, west of Morocco, forming a province of Portugal, under the name of Funchal (Map: Portugal, E 5). It consists of the island of Madeira, the small neighboring island of Porto Santo, and the islet of Deserta Grande, the last of which, together with a number of mere rocks hardly worthy of the name of islands, is uninhabited. The area of the group is 315 square miles, of which about 300 square miles are included in Madeira. The population is almost wholly confined to the island of Madeira (q.v.).

MADEIRA NUT (Portug., wood). The Persian or English walnut. See Walnut.

MADELEINE, mȧd′lân′, La. A noted church in Paris, on the square of the same name. The work was intrusted to the architect Coutant d'Ivry, and the foundation was laid by Louis XV in 1764. Upon the death of Coutant d'Ivry, in 1777, his successor, Couture, changed the design and substituted the present plan. Work on the edifice was suspended at the Revolution, and Napoleon in 1807 employed the architect Vignon to convert it into a Temple of Glory. The original name was resumed in 1816, and, after an interruption due to the revolution of 1830, the work was completed in 1832 by Huvé, at a cost of $3,000,000. The church has the form of a Roman Corinthian temple surrounded by columns, 16 of which form the south portico. It stands on a basement 23 feet high and is 354 feet in length, 141 in breadth, and 100 feet high. The tympanum of the south façade is filled with a relief by Lemaire, representing Christ as the judge of the world. The bronze doors, 34½ feet high and 16 feet broad, are by Triqueti. The interior departs from Roman prototypes in having three bays covered by pendentive domes, but each of these has an opening or *oculus* at the summit, in imitation of the Pantheon at Rome, and the interior details of columns and altars in style resemble those of the Pantheon. There are no windows. On the ceiling of the choir is a fresco by Ziegler, the "History of Christianity." The church contains a number of large paintings and sculptures. The high altar, by Marochetti, represents Mary Magdalene borne to Paradise by two angels.

MADELEINE, La. A prehistoric station near Tursac, in the valley of the Vézère, Dordogne, France, from which the Magdalenian epoch was named. See Paleolithic Period.

MADELEINE, Marie Angélique de Sainte. A prioress of Port Royal, celebrated in connection with the Jansenist controversy. See Arnauld, Jacqueline Marie.

MADEMOISELLE, mȧ′de-mwä′zĕl′. A local name about Pensacola for the fish yellowtail (q.v.).

MADEMOISELLE DE LA SEIGLIÈRE, de lȧ sâ′glyâr′. A romance by Jules Sandeau (1848), dealing with the relations between an émigré noble, the Marquis de la Seiglière, and his former tenant, Stamply. A comedy based on it was presented in 1851.

MADEMOISELLE DE MAUPIN, mô′păN′. A novel by Théophile Gautier (1835).

MADERNA, mȧ-dĕr′nȧ, Carlo (1556–1629). An Italian architect, born at Bissone near Como. As a youth, he assisted his uncle, Domenico Fontana the architect, in his work, and soon became widely known, receiving the patronage of Popes Clement VIII and Paul V. Under Paul he was appointed architect of St. Peter's, which he completed after his own designs. The Greek cross, which had been Michelangelo's plan, was altered to a Latin cross, lengthening the edifice and thereby destroying much of its harmony. The new vestibule or narthex added by Maderna is a noble design internally, but the east façade with which he fronted it is an utterly tame and inconsequential work. His portion of the work was finished in 1612; the colonnades on the Piazza in front were added by Bernini. Maderna also erected the two great fountains of St. Peter's. He grew in fame and fortune and designed churches and palaces in Spain and France as well as in other parts of Italy, but did his best work in Rome. Among various notable edifices by him in that city are the church of S. Maria della Vittoria, the Palazzo Mattei (1602), the Palazzo Odescalchi, the continuation of the Palazzo Quirinale, and the

Palazzo Barberini (completed by Bernini and Borromini).

MADERO, mȧ-dā′rō, Francisco (1873–1913). President of Mexico, born at San Pedro, Coahuila. He was a member of the large and wealthy Madero family and was well educated, liberal, and an idealist. He spent his early manhood in developing the agricultural and mineral resources of paternal estates and in the banking business. Going to Mexico City in 1900, he began to take more notice of the political situation of the country, but his real interest in politics was awakened by the election massacres at Monterey in 1903. At this time he took up the cause of the independent voters, forming the Club Democratico Benito Juarez and introducing American methods into politics. This made him the acknowledged leader of the independent voters by 1905. Opposed to the reëlection of Díaz to the presidency, in 1908 he published a book entitled *La Sucesión Presidencial en 1910*, which created a profound sensation. In the volume, while giving praise to the achievements of Díaz, he made an open attack and criticism of the then existing régime, doing so, however, in a spirit of fairness and justice. He discussed militarism and absolutism as established under Díaz, portrayed the existing evils in the social and political system, and attacked the policy of coercion in elections. His programme was "liberty of suffrage" and "no reëlection." The book was immediately suppressed and its circulation prohibited. This open attack on the administration showed Madero to be the only man who was able to run against Díaz in the election of 1910. He was nominated by the National Democratic or antireëlectionist party and proceeded to carry on a vigorous campaign in all parts of the country. The Díaz administration, fearing the consequences of such political agitation against itself, soon suppressed Madero's activity by securing his arrest at Monterey on wholly unsubstantiated charges (June 27, 1910). Having been kept in jail long enough to destroy all possible chances in the election, he was released on bail, which he forfeited. Convinced that legal methods were useless for securing reform, Madero issued the Plan of San Luis Potosí on Oct. 15, 1910. This plan demanded effective suffrage and no reëlection. It called for reforms in the distribution of land, the free restitution of the lands wrested from the Indian tribes, the liberation of all political prisoners, the abolition of the military practice of making soldiers out of condemned prisoners, and positive guaranties of the right of free speech and free press. "Take up arms, my people, drive the despots from power, recover your rights of free men," was the concluding appeal for an uprising which was set for November 29. The plot having been discovered, Madero fled to the United States, and his followers began the revolt at Puebla on November 20. Madero soon returned and took charge of the campaign, which, beginning in Chihuahua, spread at once to Sonora and Sinaloa. The successful campaign was ended by the capture of Juarez, where Madero established his capital and appointed a cabinet on May 11, 1911. Recognizing the hopelessness of the situation, Díaz entered into negotiations with the insurgents, and peace was signed on May 21. On June 7 Madero entered Mexico City. Declining the provisional presidency, he was nominated by the Progressive party and unanimously elected to the presidency on October 1. His administration was immediately beset by many difficulties. The old Congress, which he recognized, pursued a policy of obstruction, and the *Cientifico* press waged a relentless campaign against him. In 1912 revolts occurred—in the south under Zapata, in the north under Orozco, who captured Juarez, and at Vera Cruz under the leadership of Felix Díaz, the nephew of the exiled president. Under Madero's direction began the work of reform which included the rescinding of monopolistic concessions, the encouragement of labor unions, the refusal of government aid to capitalists against strikers, and the enactment of a minimum-wage law for textile workers. He was unable, however, to crush out insurrection effectively or to secure the constitutional liberties and land reforms for the oppressed peons. He neither commanded the respect nor bought the support of the army and laid himself open to charges of nepotism. On Feb. 9, 1913, a new revolt against Madero took place in Mexico City, led by General Bernardo Reyes and Felix Díaz. Bloody street fighting and bombardment of various buildings took place within the city for 10 days, at the end of which time Victoriano Huerta (q.v.) deserted Madero and caused his overthrow. Madero and the vice president Pino Suarez were arrested and forced to resign (February 19). Four days later they were both murdered, while being transferred from one prison to another, under circumstances which have never been fully explained, though it is commonly supposed that Huerta was responsible for their deaths. Huerta himself, on a visit to the United States in 1915, denied that he was responsible, but declined to incriminate anyone else. See Mexico, *History*.

MĀDHAVA, mäd′hȧ-vȧ, **MĀDHAVĀCHARYA**, mäd′hȧ-vȧ-chä′ryȧ. An eminent Hindu scholar, royal counselor, and divine, who lived in the fourteenth century of our era. He was elder brother of the famous Vedic commentator Sāyana (q.v.) and flourished under King Bukka I (1350–79 a.d.), whom he served as Prime Minister and spiritual adviser. This ruler belonged to the dynasty of Vijaya-nagara (city of victory), now Hampi, in the District of Bellary, south Central India, which is said to have been Mādhava's birthplace. He was associated with the monastery of Sringiri, of which he became abbot. The list of his works on philosophical, religious, and technical subjects is a long one. Consult Klemm, "Mādhava, seine Lehre und seine Werke," in the *Gurupūjākaumudī, Festgabe zum Doctorjubiläum Albrecht Weber* (Leipzig, 1896). The name Mādhava is frequently found earlier in Sanskrit literature and Hindu mythology as an appellation of the god Vishnu (q.v.) or his incarnation, Krishna.

MADHUCA, mä′dụ-kȧ. A tropical tree. See Butter Tree.

MA′DIA (Neo-Lat., from *madi*, the Chilean name), *Madia*. A genus of annual upright plants of the family Compositæ. The yellow ray flowers are shortly ligulate, those of the disk tubular; the seeds without pappus but very viscid, rich in oil, which is expressed. *Madia sativa*, which attains a height of 3 to 5 feet, is cultivated under the names madi or melosa in Chile, where it is native and from whence, early in the nineteenth century, it was taken to Europe, where it has been cultivated to some extent since 1839 as an oil plant. Madia oil is richer than poppy oil, almost entirely inodorous, of a bland, agreeable taste, and very suitable for oiling machines, as it does not solidify even at 10° F. The oil cake is a good food for cattle. The flowers ripen gradually in succession, so that they first ripen their seeds which fall off before the last flowers open—a great disadvantage in a crop. Another species, *Madia elegans*, is cultivated in flower gardens. A number of species of Madia are found in the Pacific Coast States from Washington southward, where they are known as tarweeds.

MAD'ISON. A village in Madison Co., Ill., 1 mile northeast of St. Louis, Mo. (Map: Illinois, D 8). Situated at the end of Merchant's Bridge, Madison is on 11 railroad lines. Car shops, steel mills, barrel works, a tie-preserving plant, rolling mills, lead works, and paving-material factories constitute the principal industrial plants. Pop., 1900, 1979; 1910, 5046.

MADISON. A city and the county seat of Jefferson Co., Ind., 86 miles southeast of Indianapolis, on the Ohio River and on the Pittsburgh, Cincinnati, Chicago, and St. Louis Railroad (Map: Indiana, G 7). It contains the Southeastern Indiana Hospital for Insane. The city has steamboat connection with important places on the river and carries on a large shipping trade, particularly in loose leaf tobacco. There are a marine railway and shipyards, ship-lumber yards, foundries and machine shops, tanneries, saw and flour mills, cotton and woolen mills, a brewery, a furniture factory, wagon shops, etc. Madison was founded in 1808, first incorporated in 1824, and received its charter as a city in 1836. The water works are owned by the municipality. Pop., 1900, 7835; 1910, 6934.

MADISON. A town in Somerset Co., Me., 27 miles by rail north of Waterville, on the Kennebec River, and on the Maine Central Railroad (Map: Maine, C 4). It contains a Carnegie library, and, among its industrial establishments, woolen, pulp, and paper. By means of two dams on the river at this place abundant water power is obtained. The electric-light plant is owned by the village corporation. Pop., 1900, 2764; 1910, 3379. Madison was first settled about 1730. At Old Point, near here, came the end of the Norridgewock Indian tribe, with the assassination of Father Rasle, in 1724. A monument has been erected to his memory. The town was incorporated in 1804.

MADISON. A borough in Morris Co., N. J., 26 miles by rail west of New York City, on the Lackawanna Railroad (Map: New Jersey, D 2). It is the seat of Drew Theological Seminary (q.v.), is popular as a suburb for Newark and New York business men, and has a public library and a fine public park, the latter having been improved at an expense of $200,000. The only important industry is that of flower culture, rose growing being the chief specialty. Madison was settled before the Revolution and was incorporated as a borough in 1889. The government is vested in a mayor, chosen biennially, and a council, elected on a general ticket. The borough owns and operates the water works and electric-light plant. Pop., 1900, 3754; 1910, 4658.

MADISON. A city and the county seat of Lake Co., S. Dak., 40 miles by rail northwest of Sioux Falls, on the Chicago, Milwaukee, and St. Paul Railroad (Map: South Dakota, G 3). It is in a picturesque lake region popular as a summer resort, is the seat of a State normal school, and contains a Carnegie library. Madison is in a farming and stock-raising district, from which it derives considerable trade, and there are several grain elevators, marble works, a flour mill, a gasoline-engine factory, and a large creamery. The water works and electric-light plant are owned by the municipality. Madison has adopted the commission form of government. Pop., 1900, 2550; 1910, 3137.

MADISON. A city, the capital of Wisconsin, and the county seat of Dane County, 82 miles by rail west of Milwaukee, on the Chicago and Northwestern, the Chicago, Milwaukee, and St. Paul, and the Illinois Central railroads (Map: Wisconsin, D 5). A widely noted educational and summer resort, it lies in the attractive lake country (at an elevation of 860 feet above the sea and 210 feet above Lake Michigan), between Lakes Mendota, Monona, and Wingra, and near Lakes Waubesa and Kegonsa. A system of beautiful parked suburban drives, carefully macadamized and nearly 30 miles in length, is maintained by popular subscription. There are also several beautiful parks, including Camp Randall Memorial, Tenney, Vilas, and Brittingham. The State House, which stands in a well-kept park, was partly destroyed by fire in 1904, and a new capitol, in the form of a cross, has been built at a cost of $7,000,000. One of the finest structures in Wisconsin is the library and museum building of the State Historical Society, opposite the State University campus; it is an Ionic, colonnaded structure, built of Indiana limestone at a cost of $700,000. The society's reference library of 371,000 volumes and pamphlets is one of the best-known American libraries. Within the building are also housed the libraries of the State University and the Wisconsin Academy of Sciences, Arts, and Letters. There are also the Legislative Reference, Carnegie, and the State Law libraries. Madison is the seat of the University of Wisconsin (see WISCONSIN, UNIVERSITY OF); it contains a United States Weather Bureau Station and a forest-products laboratory. The State Hospital for the Insane and the State fish hatchery are in the suburbs.

The city has widespread commercial interests and in its 121 industrial establishments manufactures agricultural implements, boots and shoes, gasoline and oil engines, hospital furniture, electrical machinery, machine tools, art glass, candy, carriages and wagons, and electrical appliances; there are also a beet-sugar plant and several large printing establishments. The government is administered under revised charters of 1889 and 1901, by a mayor, biennally elected, and a unicameral council which controls elections of subordinate officials. The water works are owned and operated by the municipality. Pop., 1900, 19,164; 1910, 25,531; 1914 (U. S. est.), 29,469; 1920, 38,378.

Soon after the organization of the Territory in 1836 this site was chosen for the location of the State capital; and the first house, erected in March, 1837, was for boarding and lodging the workmen on the projected capitol. In 1839 the necessary Territorial building had been built, and since then Madison (named for President James Madison) has been the regular seat of government. It was chartered as a city in 1856. Consult D. S. Durrie, *A History of Madison* (Madison, 1874), and John Nolen, *Madison: A Model City* (Boston, 1911).

MADISON, JAMES (1749-1812). First Protestant Episcopal Bishop of Virginia. He was born near Port Republic, Va., and graduated at

William and Mary College in 1772. After admission to the bar he turned to the ministry, being consecrated priest during a visit to England in 1775. He had been appointed professor of natural philosophy at William and Mary in 1773; four years later he became president of the college. In 1790 Madison was consecrated Bishop of Virginia by the Archbishop of Canterbury, in the chapel of Lambeth Palace. Thereafter he performed the duties of his episcopal office in addition to those of college president and professor. He published sermons and occasional papers and a *Eulogy on Washington*, (1800) and prepared a map of Virginia.

MADISON, James (1751–1836). An eminent American statesman, fourth President of the United States. He was born at Port Conway, Va., March 16, 1751; entered the College of New Jersey (now Princeton University) in 1769; became a notably zealous and close student of the government of the ancient republics; and after his graduation in 1771 undertook the study of law. While only 23, he served on the Committee of Safety of his county, and two years thereafter, in 1776, was a delegate to the Revolutionary Convention of Virginia. In this body he was a member of the committee appointed to draft a constitution, in connection with which work he rendered notable aid to Jefferson in his agitation for the complete toleration of all religious denominations. Madison was sent to the first Legislature elected under this constitution; in the following year he was one of the executive council, and in 1780 he was sent to the Continental Congress, where for three years he served with marked credit—insisting that Spain should allow the United States the free navigation of the Mississippi, and vigorously contending for an extension of the powers of Congress, and for prohibiting the States to issue more paper money. He again became a member of the Virginia Legislature in 1784, where he was again attentive to the problem of the relations of the States under the Confederation and strongly favored the calling of the Annapolis Convention of 1786, although for political reasons he was not a member himself. At the same time Madison, as a member of the Legislature, now successfully urged the passage of Jefferson's bill granting religious toleration, and also pleaded for sound public finance. In 1787 he was again elected to Congress, then in its decadence, and in the same year served in the Constitutional Convention at Philadelphia. In that body he was the author of what became known as the Virginia plan and throughout rendered such manifold and effective service as to win for himself the title of the Father of the Constitution. He was an untiring advocate of the principle of proportional representation in the Upper as well as the Lower House of the national Legislature. Madison coöperated with Hamilton and Jay in the production of the *Federalist* (q.v.), from 20 to 30 of the 80 papers of that work being attributed to him. Of inestimable value to the Supreme Court in the interpretation of the Constitution were the notes of the debates which he kept, and which were published by the government after his death (3 vols., Washington, 1843).

Upon his return to Virginia Madison was chosen a delegate to the Constitutional Convention called to take action on the new Constitution, and in the critical contest in that body he led the Federalists and gained a substantial victory over Henry, Mason, Lee, and the other opponents of the Constitution. The Anti-Federalists, however, were so strong in the Legislature that Madison failed in his candidacy for the Senate, chiefly through the influence of Patrick Henry, although he was elected to the first House of Representatives, defeating James Monroe, a moderate Anti-Federalist. He served in that body for four terms, until the retirement of Washington from the presidency, and as party lines were gradually drawn he became recognized as the ally of Jefferson, and as the leader in the House of the Anti-Federalist opposition to the policy of Alexander Hamilton (q.v.). He proposed the resolutions for the creation of the first three executive departments (those of State, Treasury, and War), proposed a series of amendments to the Constitution—selected from those advocated by the several States—out of which were formed the first 10 amendments as finally adopted, and took an important part in the framing of the first tariff act. The direction of business in the House was to a large extent intrusted to him. A further contribution in the formative period of the government was his insistence upon the President's power to remove his cabinet officers without the concurrence of the Senate. Upon matters involving party policy, from the time of his definite break with Hamilton, he followed the normal course of his associates, opposing Great Britain, and particularly the Jay Treaty (q.v.), refusing to approve fully the administration's policy with reference to the manner of paying the domestic debt, and taking a position of vigorous hostility to the establishment of a national bank. His enemies finally attempted, and with some success, to connect him with the questionable political journalism of Freneau and others. With Jefferson he tried to discredit Hamilton and was charged with the authorship of the Giles resolutions attacking the management of the Treasury. He warmly supported the resolution calling upon the President for the instructions given to Jay and led the attack upon the President's reply. Madison's four years of retirement (1797–1801) were broken by brief service in the Virginia Legislature (1799–1800), and by his noteworthy contribution to political literature, popularly known as the Virginia Resolutions of 1798. (See Virginia and Kentucky Resolutions.) Upon the success of the Jeffersonian Republicans in 1801 Madison was named by Jefferson as Secretary of State and retained the office throughout both terms of his chief. Two years later he was sued before the Supreme Court of the United States by a man named Marbury. The decision reached by the court is one of the most far reaching in the constitutional history of the country. For details, see Marbury vs. Madison. The administrative routine of this service was broken in the early years by the negotiations leading to the purchase of Louisiana and by the strained relations with the Barbary States. The later years, however, produced a series of problems of difficulty and importance, turning largely upon the theories maintained by England as correct principles of international law. It thus fell to the lot of Madison to direct the fruitless mission of William Pinkney to England and to take action at the time of the search of the *Leopard*. The policy of embargoes had been adopted, the war of commercial retaliation had been begun, and the conduct of England and France in regard to American commerce had reached a critical point, when the second term of Jefferson ended and the power of the "Virginia dynasty" was attested by the election to the presidency of Madison, who was Jefferson's candidate, and who received 122 out of 175 electoral votes. His first term was occupied largely by the diplomatic difficulties with England, culminating in a request for the recall of the English minister, and by the protracted dealings with France with reference to the commercial decrees of Napoleon. The anti-English faction gained control of Madison's party, and their activity, coupled with that of the younger pro-war element, finally secured the acquiescence of the President in the congressional policy of war against England. War was declared by the United States on June 18, 1812. As a war president, Madison was at his weakest, and at the outset the Americans suffered serious reverses on land. However, on the sea they won a succession of triumphs. Madison was reëlected to the presidency in 1812, receiving 128 votes, 89 being given to his opponent, De Witt Clinton, who had been set up by a coalition of Federalists and the New York wing of the Republican party. The war with England lasted almost through half of Madison's second term. Madison's presidency witnessed the complete overthrow of the Federalist organization. The old Federalist principles of a strong national government were now largely adopted by the dominant Republican party, as illustrated by the increased appropriations for the army and navy and by the reestablishment of the national bank, in all of which Madison concurred, although he differed from his party upon the warmly contested point of the propriety of making appropriations of national money for public improvements. Upon these matters, as upon the subject of the tariff, neither sectional nor party lines were permanently drawn in Madison's time. Upon his withdrawal from public service Madison retired to Montpelier, Va., where after a period of 20 years of quiet and leisure he died (June 28, 1836). In later life he took much interest in popular education and devoted himself to promoting the interests of the University of Virginia. His last public service was in the Virginia Constitutional Convention of 1829. His wife, formerly Mrs. Dorothea (familiarly known as "Dolly") Payne Todd, who lived until 1849, was for many years a conspicuous figure in Washington society.

Mahan, *Sea Power in its Relations to the War of 1812* (2 vols., Boston, 1905); A. C. McLaughlin, *The Confederation and the Constitution* (New York, 1905); K. C. Babcock, *Rise of American Nationality* (ib., 1906); Edward Channing, *The Jeffersonian System* (ib., 1906); Hannis Taylor, *The Real Authorship of the Constitution of the United States Explained* (Washington, 1912); J. G. Wilson (ed.), *Presidents of the United States*, vol. i (New York, 1914). There is a biography of Mrs. Madison by M. W. Goodwin (New York, 1896).

MADISON BARRACKS. A United States military post in New York, established in 1813 and occupying a reservation of 107.72 acres, on Black River Bay, 10 miles from Lake Ontario, adjoining Sackett's Harbor. A rifle range of 868 acres has been established at Stony Point, 16 miles from the post. The usual garrison consists of the headquarters and two battalions of an infantry regiment, with necessary sanitary and supply troops.

MADISON SQUARE GARDEN. One of the largest buildings devoted to amusement in the city of New York. It contains an amphitheatre accommodating 15,000 people and used for horse shows, circuses, bicycle races, and similar purposes, a theatre, a concert and ball room, a restaurant, a roof garden, and a number of studios. The building is notable for its great tower, over 300 feet in height, modeled after the Giralda at Seville. See Plate of SEVILLE.

MAD′ISONVILLE. A city and the county seat of Hopkins Co., Ky., 38 miles south of Henderson, on the Louisville and Nashville and the Kentucky Midland railroads (Map: Kentucky, C 5). It is the centre of a fine agricultural and coal country and has an important tobacco trade and saw and planing mills, flour mills, a tobacco factory, tobacco stemmeries, coal mines, etc. The water works, sewage system, and electric-light plant are owned by the city. Pop., 1900, 3628; 1910, 4966.

MADISONVILLE. Formerly a village in Hamilton Co., Ohio, now part of Cincinnati. It is essentially a residential place. Near here are the Madisonville Prehistoric Cemetery and the Turner group of earthworks, both the property of Harvard University.

MÄDLER, mā′dlẽr, JOHANN HEINRICH (1794–1874). A German astronomer, born in Berlin. He began to study natural science at the University of Berlin in 1822 and in 1830 was appointed an instructor in the Berlin Normal School. As the result of his astronomical observations, he published a map of the moon in 1834–36 and immediately afterward was chosen assistant in the Berlin Observatory. In 1837 he published his *Allgemeine Selenographie*, and in 1840 was made director of the observatory at Dorpat, Russia. There he made extensive researches in regard to the fixed stars and in 1846 published *Die Centralsonne*, propounding the theory that the centre of the stellar universe is located in the Pleiades. In 1865 he returned to Germany. His further publications include: *Fragments sur les corps célestes du système solaire* (1840); *Populäre Astronomie, oder Wunderbau des Himmels* (1841; 8th ed., 1885); *Untersuchungen über die Fixsternsysteme* (2 vols., 1847–48); *Astronomische Briefe* (1844–46); *Der Fixsternhimmel* (1858); *Geschichte der Himmelskunde* (2 vols., 1872–73).

MADNESS. See INSANITY; LUNACY.

MAD′OG (commonly **MADOC**) **AP OWEN GWYNNEDD**, gwĭn′nĕᴅ (c.1150–?1180). A Welsh prince and the reputed discoverer of America. The story is that Madog was compelled by civil strife to leave his native land, that he sailed westward in 1170, and reached a new land whose productions and inhabitants were quite unlike those of Europe. This land is assumed to have been America. He returned to Wales, equipped a second expedition and set sail again, but never returned. The earliest extant mention of Madog is in a poem by Maredudd ap Rhys, who lived in the middle of the fifteenth century. No reference is made to discoveries in the West. In 1584 Dr. David Powel edited and published Humphrey Llwyd's [or Lloyd] translation of *Brut y Tywysogion*, with additions of his own, under the title of *The Historie of Cambria*, and first gave the story of Madog's alleged discovery to the world. Very probably he found the adventure in Llwyd's work. There is no mention of Madog in the original Welsh *Brut y Tywysogion*. The theory of a Welsh discoverer of America was received with considerable enthusiasm in Wales, but during the last century its adherents have gradually disappeared. Some arguments in its behalf, derived from words in the Indian languages supposed to resemble Welsh, and from the reports of a tribe of fair-haired and light-skinned Indians, assumed to be descendants from Madog's colonists, may be found in Catlin, *North American Indians* (ed. 1854). Consult: John Williams: *An Enquiry into the Tradition Concerning the Discovery of America by Prince Madog ab Owen Gwynnedd* (London, 1791); George Burder, *The Welsh Indians; or a Collection of Papers Respecting a People whose Ancestors Emigrated from Wales to America in the Year 1170 with Prince Madoc* (ib., 1797); Thomas Stephens, *Madoc: An Essay on the Discovery of America by Madoc Ap Owen Gwynedd in the Twelfth Century* (ib., 1893). Powel's edition of Lloyd or Llwyd was reprinted in London in 1811.

MADON'NA (It., my lady). A word specially applied to the Virgin Mary which has become common in other languages than the Italian, particularly to describe the Virgin in works of art. Early Christian art only very occasionally portrayed the Virgin. If alone, she stood with arms extended in prayer, as emblematic of the Church or the Saved Soul: this figure of the *Orans* (praying figure) is sometimes inscribed Virgo Maria, but not in the earliest examples. The Virgin enthroned and holding the Child did not become popular until after the Council of Ephesus in 431 had declared her the Mother of God. Byzantine art of the sixth and following centuries created the type of Youthful Virgin that was to be retained in art up to the Renaissance. The apocryphal lives of the Virgin and of the Child Christ, so popular in literature, furnished themes for art, among the earliest being the scenes in the mosaics of Santa Maria Maggiore in Rome (c.432). Characteristically the color of her robe was blue, starred or slashed with gold, and it was represented draped over her head. As Christian iconography (q.v.) developed, the scenes in which the Virgin figured increased, coming at last to include all the recorded events of her earthly life. Later her death (described by Pseudo-Dionysius c.500 A.D.) and her ascent into heaven also became art themes. Finally, in the Last Judgment and scenes from the Apocalypse, she appears, usually as intercessor, at the side of Christ.

There is an uninterrupted series of paintings and sculptures from the time of the mosaics of Sant' Apollinare Nuovo at Ravenna to the Gothic period, showing how systematically Byzantine art created a Life of the Virgin, and how mediæval Western art borrowed these scenes and developed them. It remained for Gothic art to embody the further apotheosis of the Virgin so characteristic of the age of the Troubadours and the Minnesingers, of St. Bernard and of the cathedrals all dedicated to the Virgin. She is there represented, as in the mosaic of Santa Maria in Trastevere (c.1140) or the fresco by Orcagna in the Campo Santo at Pisa, or the sculptured portal of Notre Dame in Paris, as raised into the divine sphere by the side of her Son. Raphael's Sistine Madonna is one of the most beautiful later representations of her as Queen of Heaven. Murillo portrays another favorite theme of the late Renaissance, the Virgin as the woman of Revelations with the moon or the globe under her feet, and especially her Immaculate Conception. At a still later period came the Virgin of the Seven Sorrows, with pierced heart.

It was during the Gothic period that the devotion to the Virgin developed the artistic scene of the Virgin and Child, the scene most often repeated in art between the thirteenth and sixteenth centuries. Cimabue and Duccio painted its most beautiful early examples. Fra Angelico, Filippo Lippi, Ghirlandaio, Giovanni Bellini, Perugino, and a host of other painters followed in the fifteenth century. The scene, which was at first very simple, the Virgin and Child being accompanied merely by angels or adored by the Magi or Shepherds, became complicated. The Magi were accompanied by a caravan of attendants; St. John, St. Catharine, and other figures were introduced, as has been explained under HOLY FAMILY, and saints and fathers of the Church were added in the principal or in accessory scenes.

When applied to a painting or a sculptured group, the term Madonna usually signifies a representation of the Virgin and the Christ Child, either alone or accompanied by saints, who are, however, accessories to the principal subject. It is to be distinguished from such similar themes as the Holy Family (q.v.), the Mater Dolorosa, or the Immaculate Conception. The best-known Madonnas were painted by Italian artists, by whom the theme was chiefly developed.

The emancipation from the stiff Byzantine type of the Madonna was effected in the latter part of the thirteenth century by a number of Italians, chief among whom was Cimabue (q.v.). The best examples of his Madonnas are in San Francesco, Assisi, the Florentine Academy, and the Louvre. While retaining the gold background and the stiff Byzantine type, they show many natural motifs. His younger contemporary, Duccio of Siena, went much further, achieving a more ideal, if freer type, as may be seen in his chief work, the altarpiece of the cathedral of Siena, still preserved there. Fra Angelico (1387–1455) repeatedly treated the subject, the best-known examples being the "Madonna of the Star," in the convent of San Marco (for illustration, see ANGELICO), and the life-size "Madonna Enthroned," surrounded by the well-known angels (Uffizi, Florence)—both severely archaic in treatment. The first artist to break with this conventional treatment was Fra Filippo Lippi, who portrayed the Madonna and Child as the incarnation of maternal love and childish innocence. One of his best-known examples is the beautiful "Virgin Worshiping the Child," lying on a flowery sward in a summer landscape (Berlin Museum); another, in the Uffizi, represents two little angels lifting the Child to the Madonna, who is engaged in devout meditation. The characteristics of Sandro Botticelli's (q.v.) art are nowhere more delightfully revealed than in his Madonnas. Of the two charming circular specimens in the Uffizi, the "Magnificat" is the most representative of his early manner, while its companion piece holds the same rank for his later period. Both represent the Virgin crowned and adored by dreamy angels.

Of Leonardo da Vinci's Madonnas but two probable specimens survive, "La Vierge aux rochers" and the "Madonna with St. Anne," a very unusual though charming representation, in which St. Anne sits in the Virgin's lap. (For description of his other Madonnas, see VINCI, LEONARDO DA.) Michelangelo twice painted the subject—an unfinished Madonna in the British Museum, and the "Madonna of Angelo Doni," in the Uffizi, remarkable for the novel action of Joseph passing the Child to the Madonna over her shoulder, and for the manner in which the background is filled with nude youths. The best-known examples of Andrea del Sarto's Madonnas are the "Madonna del sacco," a fresco over the portal of the cloister of the Annunciata (Florence), so called for the sack upon which Joseph leans, and the "Madonna dell' arpie," which derives its name from the harpies on the pedestal, upon which the Virgin leans. See SARTO, ANDREA DEL.

In the Madonnas of the Umbrian school its dreamy sentiment and ecstatic piety are most strikingly revealed. There are good examples by Perugino in the Uffizi, in the Vienna Gallery and elsewhere; but the best known is the "Enthroned Madonna and Child," surrounded by the patron saints of Perugia, now in the Vatican. Of the Ferrarese work of the fourteenth century it is sufficient to mention the fine altarpiece by Francesco Cossa in the gallery of Bologna, and those of Lorenzo Costa in the church of San Giovanni in Monte (Bologna) and in the Berlin Museum. The altarpiece of Sant' Andrea by Dosso Dossi (sixteenth century), now in the Gallery of Ferrara, representing the "Madonna Enthroned," surrounded by saints, with John the Baptist at the foot of the throne, is one of the best works, both in color and treatment, of Italian art. At Bologna Francia produced a number of Madonnas, celebrated for their mild, reproachful expression, of which the best known are in the gallery there: a "Madonna Enthroned," and the "Virgin in a Rose-Garden," adoring the Child. The best-known Madonnas of Mantegna are the grand altarpiece of San Zeno, Verona, the example in the National Gallery (London), and, most of all, the "Madonna della vittoria" in the Louvre. (For description, see MANTEGNA.) Among the Madonnas of Correggio one in the Uffizi, "La zingarella" (the Madonna as a gypsy), in the Naples Gallery, and the fine example in the National Gallery, represent domestic scenes; more ambitious attempts are the "Madonna with St. Francis" (Dresden) and the famous "Giorno" (day) in the Parma Gallery. See CORREGGIO.

The Madonnas of the Venetian painters of the fifteenth century unite Paduan virility of execution with Venetian charm of color. Especially beautiful are those of Giovanni Bellini, numerous in the Venetian Academy, the Berlin Gallery, and the Brera (Milan). The most imposing examples are a series of great altarpieces, formerly in the churches of Venice, now partly in the Academy, the grandest of which are the "Frari Madonna" (for description, see BELLINI), the altarpiece of San Giobbe (Venetian Academy), and the splendid altarpiece of San Zaccaria. Only one of Giorgione's Madonnas survives, the "Castelfranco Madonna," in the cathedral of that town. The head of the Virgin, who is seated upon a high throne, is of the purest and most pathetic beauty. On her right is San Liberale in full armor, an ideal of knighthood, and to the left is St. Francis. Above a wall in the background may be seen a fair and sunny landscape. Among Titian's (q.v.) Madonnas there are well-known examples at Vienna (including the "Madonna with the Cherries"), at Dresden, in the Louvre, the Uffizi, and the Prado (Madrid). The most celebrated and grandest, however, is the Pesaro Madonna, in the church of the Frari, Venice.

The chief of all Madonna painters, the one who developed the subject to its fullest extent, was Raphael. In his early period he painted a dreamy and sentimental type, the highest development of the Umbrian ideal; in the middle or Florentine period he used the theme to portray the relation of mother and child, while in the Roman he combined with this motif the nobler concept of the Queen of Heaven. Of the large number ascribed to him, over 50 merit consideration; but many of these, especially during the Roman period, were executed by his pupils. Of his earliest period there are two good examples at Berlin, after drawings by Pinturicchio, but the "Connestabile Madonna" (St. Petersburg) is assuredly the finest. The Virgin sits reading in a garden, the Child in her arms; the picture is almost miniature in size and delicate in finish. A more ambitious example, "the Colonna Raphael," in which she is represented surrounded by four saints, is now in the Morgan collection (Metropolitan Museum, New York).

An early work of the Florentine period—perhaps the best and certainly the most popular example—is the "Madonna del Gran Duca" (Pitti Palace, Florence), so called because it was the favorite of the Grand Duke. The Virgin stands erect holding the Child and is statuesque in character and well modeled. Similar in pose is the "Madonna Tempi" (Munich), while those known as the "Colonna" (at Berlin), "Orléans" (Duc d'Aumale), and "Panshanger" (at Panshanger) Madonnas represent the Virgin as seated. All of these have been much damaged by restoration. Another favorite type represents the Virgin as seated in a meadow landscape with the infant Christ and St. John, of which the best examples are the "Madonna in the Meadow" (Vienna); the "Madonna der cardellino" (Uffizi), so called because John presents a goldfinch to the Virgin; and, most perfect of all, "La belle jardinière," in the Louvre. (See RAPHAEL.) Of his more ambitious altarpieces the chief are the "Blenheim" or "Ansidei Madonna" (1505, National Gallery, London), one of the best preserved of Raphael's works, in which the enthroned Virgin is represented between St. John and St. Nicholas of Bart; and especially the "Madonna del baldachino." See RAPHAEL.

The best-known Madonnas of Raphael's Roman period are the "Aldobrandini (Garvagh) Madonna" (National Gallery); the "Madonna col divin amore" (Naples); the "Madonna with the Diadem" (Louvre), probably executed after Raphael's design by Giulio Romano. Of the circular type the best known are the "Madonna della candelabra" (National Gallery), executed by a pupil; the beautiful "Madonna Alba" (St. Petersburg); and, chief of all, the "Madonna della sedia" (of the chair), vying with the Sistine in popularity. He found time also to paint three large altarpieces, the "Madonna di Foligno" (Vatican), in which the Virgin is enthroned in the clouds, with saints and the donor below, while the background is filled with the representation of Foligno struck by a thunderbolt. Another famous example is the "Madonna del pesce" (Madrid), so called from the fish which Tobias, escorted by the Angel, presents to the Madonna; this was executed in part by Giulio Romano. But grandest of all, the culmination of Raphael's Madonnas, and the most perfect representation of the Queen of Heaven in art, is the Sistine Madonna. See RAPHAEL for illustration and description.

Many of Raphael's Madonnas during this period were only designed by him and executed by his pupils, especially by Giulio Romano; as, e.g., the "Madonna del impannata" (windowpane), in the Pitti Palace, the "Madonna del passeggio," in Bridgewater House (London), and the "Madonna della gatta" (cat), in the Museum of Naples. Besides the works executed after the designs of Raphael, Giulio Romano designed Madonnas of his own, the best known of which, the "Madonna della catina" (Dresden), is so called because of the basin in which the Christ Child is being bathed. In general, the Madonnas of the Mannerist and Eclectic schools are of little interest, on account of the lack of real depth of feeling.

In northern Europe fewer examples of "Madonnas" survive, owing in part to the Iconoclastic storms which devastated the churches. Though realistic in type, those of the Early Flemish and German schools do not endeavor to represent the subject as a mere family scene, but retain much of the mediæval dignity. Among the best examples by Jan van Eyck are the "Madonna of Canon van der Poel" (Bruges); the "Virgin in a Gothic Chapel," reputed part of a traveling altar of Charles V, at Dresden; the "Lucca Madonna," suckling her Child (Frankfort), and the famous Madonna of Chancellor Rollin (Louvre). All the other great Flemish masters, Rogier van der Weyden, the Master of Flémalle, Hugo van der Goes, Hans Memling, Gerard David, and Quinten Matsys, delighted in rendering the same theme.

Stephan Lochner's Madonna in the great altarpiece of Cologne Cathedral and other representations of the same subject are gems among the works of the early German school, soft and idyllic in character, while the same subject by Schongauer, in the church of St. Martin, Colmar, is more solemn and grandiose. Dürer's "Madonna with the Pear" (Imperial Gallery, Vienna) is his chief representation of the subject. First in rank among all German Madonnas, as the Sistine among Italian, is the "Madonna of Burgomaster Meyer" at Darmstadt. (For description and illustration, see HOLBEIN.) The great Dutchmen of the seventeenth century were little concerned with Madonnas, the Flemings somewhat more so. The best example by Rubens is the beautiful "Madonna of the Innocents" (Louvre), in which she is portrayed as surrounded by crowds of innocent children; while in Van Dyke's "Madonna of the Rosary" (Oratorio del Santissimo Rosario, Palermo), cherubim and saints surround the Virgin, holding the rosary to St. Dominic.

Among Spanish painters Murillo's Madonnas are of rare coloristic charm and deep religious feeling. Some of the finest examples, representing only the Virgin and Child, are in the Pitti (Florence) and Corsini (Rome) palaces, while in the grand example of the Louvre St. Elizabeth and St. John are also represented. Murillo is especially known for his supernatural aspects of the Madonna, as her Assumption and Immaculate Conception. Madonnas in contemporary art are of less interest, because they are no longer the highest expression of the religious spirit of the day. Prominent among German examples are those by Overbeck (New Pinakothek, Munich), a reflection of the old Umbrian type; of Bodenhausen, Defregger, and Max (Leipzig Museum). The best among the French are Bouguereau's "Madonna of the Angels" and "La Vierge consolatrice" (Paris, Luxembourg), and Dagnan-Bouveret's "Virgin in the Carpenter Shop."

Hardly less than in painting, the subject was a favorite one with the sculptors of Christian art and with the ivory carvers of the Romanesque and Gothic epochs. It was rendered times almost innumerable by the stone sculptors of the Middle Age, appearing on the exterior or in the interior of every cathedral rejoicing in sculpture: at Naumburg (Saxony), Notre Dame de Paris, Chartres, Rheims, etc. That the sculptors of these sublime works are unknown, makes them none the less valuable from the æsthetic point of view. During the Middle Age in Italy it was a favorite theme with the Pisan school, the most powerful versions being by Giovanni Pisano in the cathedral of Prato and the baptistery of Pisa. During the Renaissance its popularity continued, as may be seen in the reliefs of Donatello, and in the exquisite terracotta reliefs of Luca della Robbia (q.v. for illustration) and his followers; of these reliefs there are numerous examples in the Museo Nationale and elsewhere in Florence. The most celebrated examples of a sculptured Madonna are Michelangelo's "Madonna of Bruges," in the cathedral of that city—a beautiful example of his early or realistic period—and the incomparable "Pietà" of St. Peter's. See MICHELANGELO.

Bibliography. Popular books on the Madonna in art are by Mrs. Jameson, *Legends of the Madonna* (London, 1857), and E. Hurll, *The Madonna in Art* (Boston, 1898). A scholarly work, especially important for the earlier periods, is Rohault de Fleury, *La Sainte Vierge* (Paris, 1878); also Baumbach, *Die Madonnendarstellung in der Malerei* (2d ed., Dresden, 1906). The best work on the subject, both as to critical value and illustrations, is Adolfo Venturi, *La Madonna* (Florence, 1900), which, however, is confined to Italian Madonnas; also Ferrigni, *Madonne fiorentine* (Milan, 1912). For the early Netherlands school: Siebert, *Die Madonnendarstellung in der altniederländischen Kunst* (Strassburg, 1906). For the German school: Fäh, *Das Madonnenideal in den ältern deutschen Schulen* (Leipzig, 1884); also F. A. Gruyer, *Les Vierges de Raphael et l'iconographie de la Vierge* (Paris, 1869); Karoly, *The Madonnas of Raphael* (London, 1894). See Plates of ANGELICO; CORREGGIO; ENGRAVING; HOLBEIN; RAPHAEL; ROBBIA; SARTO.

MADOQUA, mä′dô-kwȧ. The native name for a species of antelope in Abyssinia. See BENI-ISRAEL; DUIKER.

MA'DOR, SIR. A Scottish knight who accused Queen Guinevere of poisoning his brother. Her part was espoused by Lancelot of the Lake, who slew Mador in a combat and received as a reward the castle thereafter known as the Joyeuse Garde.

MADOU, mȧ'do͞o', JEAN BAPTISTE (1796–1877). A Belgian genre painter and lithographer. He was born in Brussels and studied under P. S. François. He first excited attention with his drawings and lithographs of the ancient and modern costumes of the Low Countries, scenes in the lives of the Flemish and Dutch painters, and in particular his *Physionomie de la société en Europe depuis 1400 jusqu'à nos jours* (1836). In 1842 he began to paint scenes of popular life in the costumes of the seventeenth and eighteenth centuries, displaying facile invention and a rather superficial humor. His very numerous paintings are executed with much detail in a smooth and uninteresting technique. He is represented in the Brussels Museum by the "Rat Hunt" and other paintings, in the Antwerp Museum, and in the private collections of Europe and America. He also painted decorations in the royal castle of Ciergnon and was a member of the Antwerp Academy.

MADOX BROWN, FORD. See BROWN, FORD MADOX.

MADOZ, mä'dōth, PASCUAL (1806–70). A Spanish statesman, jurisconsult, and author, born at Pamplona and educated in law at Saragossa, where he won his degree of licentiate in a brilliant examination. Despite this and his having served as one of the defenders of Monzón against the French in 1823, and having been a prisoner for several months in the hands of the French, his university soon expelled him, charging that he held Jansenist ideas. Owing to a decree of Calomarde forbidding any one to practice law who was not 25 years old, he went to France and remained at Tours until the amnesty proclaimed by María Cristina permitted his return. He began the practice of law at Barcelona and edited the *Diccionario geográfico universal* (1829–34) and a *Colección de causas célebres* (1840). He became prominent in politics, was appointed a judge, and was elected a member of the Cortes. There he opposed Espartero and ultimately became the leader of the Progressist party. In 1854 he was Governor of Barcelona, in 1855 was Minister of Finance, and in 1856, because of his liberal views, was obliged to leave Spain. Returning, he was active in the revolution of 1868, was Governor of the Province of Madrid, and was a member of the Cortes. He died while accompanying the Spanish deputation to Rome to offer the crown of Spain to Amadeus. His important *Diccionario geográfico estadístico y histórico de España* was published in 1848–50.

MAD PARLIAMENT OF OXFORD. The name given by the adherents of Henry III to the Parliament which assembled June 11, 1258, at Oxford. In the attempt to obtain for his second son, Edmund, the throne of Manfred (q.v.), King of Naples, Henry III had become heavily indebted to the papacy. The Great Council, however, had refused to grant the necessary money without a redress of grievances, and the King was compelled to give his consent for the appointment of a committee of 24, chosen half from the King's party and half from the barons'. The 24 drew up a series of grievances which were presented to the Mad Parliament, and the Provisions of Oxford (q.v.) were framed. Consult Stubbs, *Constitutional History*, vol. ii (4th ed., Oxford, 1896), and H. W. C. Davis, *England under the Normans and Angevins* (New York and London, 1905). See MONTFORT, SIMON DE.

MADRAS'. A province of British India, formerly the Presidency of Madras (Map: India, C and D 6). It occupies, together with its tributary states, the southern part of the Indian Peninsula, being irregularly bounded on the north by Bengal and the Central Provinces, and on the northwest by Bombay, Mysore, and Hyderabad. The province under direct British administration is divided into 22 districts, with a total area of 142,330 square miles; pop., 1891, 35,630,440; 1901, 38,209,436; 1911, 41,405,404. The native states of Travancore, Cochin, Padukkottai, Banganapalle, and Sandur, politically controlled by Great Britain, cover an area of 10,084 square miles; pop., 1891, 3,700,622; 1901, 4,186,967; 1911, 4,811,841. The surface consists of a high plateau land encircled by mountain ranges, the Eastern Ghats extending in a southwestern direction until they merge in the Nilgiris, which are connected with the Western Ghats (qq.v.). A long and broad plain lies between the Eastern Ghats and the shores of the Bay of Bengal, generally known as the Coromandel coast (q.v.), and a narrow plain interspersed with lagoons extends between the Western Ghats and the Malabar coast (q.v.) on the Arabian Sea. The principal rivers, the Godavari, Kistna, and Kavery, all rise in the Western Ghats, and traversing the plateau break through the Eastern Ghats and flow into the Bay of Bengal. The soil of the plateau generally is fertile, and the irrigation systems of the Godavari and Kistna have yielded good returns to the government; the coast lands are sandy and, except in the deltaic regions, sterile. The climate varies according to elevation; on the whole, it is sultry but fairly healthful. While on the west coast the rainfall is usually excessive, in the interior it is generally inadequate, being in the rain shadow of the Western Ghats, and its failure has been the cause of occasional famines; extensive irrigation works have been constructed in the attempt to modify this evil. Forests of teak, sandalwood, eucalyptus, ebony, and rosewood, under reservation rules, cover about 18 per cent of the surface. The chief wild animals are the elephant, gayal (a species of cattle), black leopard, and ibex. The principal minerals are iron, copper, lead, antimony, and silver, while gold, garnets, and diamonds are found in paying quantities, and salt is largely manufactured on the coasts by evaporation. Although there have been many reports of coal discoveries, there are no important workable seams.

Agriculture. The population of the presidency is largely agricultural. But returns from the soil are in general much less satisfactory than in various other parts of India. Agricultural conditions west of the Western Ghats, in the districts of Malabar and South Kanara, are notably different and better than in the greater part of the presidency east of those mountains. In the Malabar Coast (q.v.) the southwest monsoon, with its rain, is unfailing, and agriculture flourishes. East of the Western Ghats, except in favored tracts, as in the great deltas, the rainfall and water supply are uncertain, variable, and often scanty, the atmospheric humidity is generally slight, and over vast areas the soils are shallow, gravelly, or sandy. In these conditions successful agriculture demands the unceasing and intelligent application of scientific methods. "Yet," says a well-informed writer on the subject, "in practice tillage is defective; stock are productively inadequate and largely ill cared for; cattle-power implements, though ingenious, are primitive, and in the Tamil districts almost absent; manures are low in quality and gravely insufficient in quantity; capital is scanty and credit too frequently mortgaged; the ryot is too isolated a unit; and, though hereditary skill is considerable, there is lacking that basis of wider knowledge which alone renders possible an intelligent adaptation or development of practice to meet new conditions, which have swiftly supervened upon a rapid increase of population over unimproved soils and the opening up of trade." The only effective remedy is irrigation, and this is necessarily partial and inadequate, although the government has dammed many rivers, constructed large canals, and built thousands of tanks or reservoirs, and both public and private enterprise has made literally hundreds of thousands of permanent wells. The net area cropped in British territory has been reported as follows: average during the years 1884–85 to 1889–90, 22,201,000 acres; 1890–91 to 1899–1900, 23,872,000 acres; in 1903–04, 25,857,300 acres; in 1911–12, 33,068,400. In addition to the last figure there were reported for 1911–12, 8,935,100 acres of current fallows, 9,371,400 of cultivable waste other than fallow, 24,899,500 not available for cultivation, and 12,798,200 forest. Of the net area cropped in 1911–12, 4,311,700 acres were cropped more than once, so that the total area cropped is reported at 37,380,100 acres. Of this area, to food grains and pulses were planted 28,586,300 acres (including rice 10,289,500, great millet 5,166,300, spiked millet 3,383,600, millet 2,448,400); oil seeds, 2,927,400; cotton, 2,675,800; condiments, 720,700; tobacco, 192,200; indigo, 90,300; coffee, 51,100; tea, 21,100. In 1911–12 irrigation was practiced on 9,586,900 acres (net), planted chiefly to rice. Of the total irrigated area, 3,534,800 acres were irrigated by government canals, 179,600 by private canals, 3,298,700 by tanks, 1,442,300 by wells, and 1,131,500 by other sources.

Other Industries, Commerce, etc. The native cotton-manufacturing industry, which was widely developed in former years, has greatly diminished under foreign competition. For 1911–12, 20 cotton mills were reported, and the output of yarn 42,838,000 pounds, as compared with 203 mills and 590,842,000 pounds for all British India. The manufacture of cigars has acquired some importance. In a few places ivory carving has become important, and the old occupation of metal working still has a considerable following. Salt is extensively produced along the east coast, but under a government monopoly. Some indigo is manufactured. The trade of the province suffers from the want of adequate harbor facilities on the east coast. Much of the trade is by rail to Bombay and other large trading centres. In the foreign trade imports and exports of private merchandise increased from £4,802,403 and £8,736,782, respectively, in 1902–03 to £6,836,583 and £12,513,891 in 1907–08 and £7,794,808 and £15,400,446 in 1911–12 (total for British India, in 1911–12, £92,383,255 and £151,896,113). The leading imports include cotton piece goods and yarn, metals, hardware and machinery, railway material, and apparel; principal exports: cotton and cotton piece goods, hides and skins, grain and pulse, coffee, seeds, spices, and tea.

Population. The population in British territory has been returned as follows: in 1871, 31,220,973; in 1881, 30,87,218 (the decline of about 1.5 per cent was due to the famine of 1876–78); in 1891, 35,630,440 (increase, about 15.7 per cent); in 1901, 38,229,654 (7.3); in 1911, 41,405,404 (8.3). The Madras native states are Travancore, Cochin, Puddokotai, Banganapalle, and Sandur. The number of inhabitants in British territory, in the native states, and the total, with decennial increase per cent, are shown below for 1901 and 1911:

	1901		1911	
	Number	Increase	Number	Increase
British territory	38,229,654	7.3	41,405,404	8.3
Native states	4,188,086	13.2	4,811,841	14.9
Total	42,417,740	7.8	46,217,245	9.0

In 1911 there were in British territory 20,382,955 males and 21,022,449 females; of the males and females respectively, the unmarried numbered 10,862,162 and 7,832,583; married, 8,734,806 and 9,286,460; widowed, 785,987 and 3,903,406. There is an extraordinary diversity of languages in Madras, although the great mass of the people speak either Tamil or Telugu. In 1901 Tamil was the vernacular of about 15,183,000; Telugu, 14,277,000; Malayalam, 2,861,297; Kanarese, 1,519,000 (these four belong to the Dravidian subfamily of the Dravido-Munda languages); Oriya, 1,809,000; Hindustani, 880,000; others, 1,687,000. The Dravidians are dolichocephalic and of medium stature, with dark (almost black) skin, curly (but not woolly) hair, and high nasal index. The following table shows the population by religion in 1911:

	British territory	Native states	Total
Hindus	36,806,978	3,321,757	40,128,735
Sikhs	7	....	7
Jains	26,995	150	27,145
Buddhists	693	16	709
Parsis	488	10	498
Mohammedans	2,740,408	314,498	3,054,906
Christians	1,191,259	1,154,209	2,345,468
Jews	71	1,248	1,319
Animists	638,463	19,953	658,416
Others	42	......	42
Total	41,405,404	4,811,841	46,217,245

Christians in British territory increased from 1,024,071 in 1901 to 1,191,259 in 1911; in the native states, from 910,409 to 1,154,209; and in British territory and native states combined, from 1,934,480 to 2,345,468. A very large proportion of Indian Christians are in Madras. The number in British India increased from 1,904,401 in 1901 to 2,492,277 in 1911; and in British India, together with all the native states, from 2,923,241 to 3,876,196. By sect, most of the Hindus are followers of Vishnu or Siva, the former predominating in the Telugu country and the latter in the extreme south; in the western Deccan many of them are Lingayats.

The people live mostly in villages of only a few hundred inhabitants each. The only large cities or towns are Madras, the third largest city in India, with 518,660 inhabitants in 1911 (increase over 1901, 1.8 per cent); Madura, 134,130 (22.2); Trichinopoly, 123,512 (16.5); Calicut, 78,417 (1.9); Salem, 59,153 (decrease, 17.8).

Education. In 1911 the educational condition of the people was as follows:

		British territory	Native states	Total
Illiterate. . .	Males. .	17,572,747	1,836,475	19,409,222
	Females	20,739,097	2,286,544	23,025,641
Literate. . . .	Males. .	2,810,208	575,283	3,385,491
	Females	283,352	113,539	396,891
Literate in English. . .	Males. .	247,392	33,942	281,334
	Females	27,233	4,764	31,997
Total population. . . .	Males. .	20,382,955	2,411,758	22,794,713
	Females	21,022,449	2,400,083	23,422,532

Notwithstanding the fact that the great majority of the people are illiterate, steady progress is noted in public education. In 1911–12 there were in public colleges 5752 male students and 49 female; in public schools, 937,617 male pupils and 209,468 female; in private institutions, advanced and elementary, 110,011 male students and 17,168 female; total, 1,053,380 male and 226,685 female, as compared with 884,848 male and 172,322 female in 1907–08. The total number of educational institutions in 1911–12 was 31,052, with 1,280,065 scholars; of these, 1,233,161 were studying a vernacular language, 89,660 a classical language, and 156,110 English. Among the leading educational institutions are the Madras University, Madras Christian College, Presidency College, Pachayyappa's College, a law college, an engineering college, a medical college, and a school of arts—all at Madras; the government arts colleges, at Rajahmundry and Combaconum; a teachers' college at Saidapet; and a college of agriculture at Coimbatore.

Government. The Governor is appointed by the crown. Also appointed by the crown is his executive council, which consists of two members of the Indian Civil Service and an Indian member; the Secretary of State for India may increase the number to four. There is a legislative council of 48 members, official or elective. Each of the 26 districts into which the province is divided is administered by a collector and inferior officers. Unlike other provinces, the districts are not grouped into commissionerships. There are district and subdistrict boards and village committees. In the fiscal year 1911–12 the revenue of Madras amounted to 14,83,11,494 rupees and the expenditure to 7,98,73,223 rupees. The most important source of receipts is the land revenue, which amounted to 5,65,32,986 rupees. In addition to the provincial revenue and expenditure are those of the municipalities and district boards. The ordinary receipts and disbursements of the municipalities in 1911–12 were 84,81,000 and 83,83,000 rupees respectively; of the district boards, 1,49,73,000 and 1,30,58,000 rupees.

History. Anciently the province was divided into several kingdoms, of which the chief were Telingana on the northeast, Karnataka on the west, and the Tamil principalities of Pandya, Chola, and Chera in the south. Splendid architectural monuments, stone and brass inscriptions, and imaginative traditions attest their former existence. Authentic history begins with the Mohammedan invasion of the fourteenth century, when Ala ud din conquered the kingdoms of Karnataka and Telinga. After the Mohammedan evacuation the native dynasty of Vijaynagar dominated until 1565, when it was overthrown by the Deccan Mohammedans; later the country again became divided into principalities, of which the more prominent were the Carnatic, Mysore, and Tanjore. After the first visit of Vasco da Gama, in 1498, Madras was one of the principal battle grounds of the Portuguese, Dutch, French, and British in the struggle for supremacy. The English under Clive and Coote drove out the other Europeans, but it was not until the close of the nineteenth century that native uprisings were completely checked.

MADRAS'. A seaport city, capital of the Madras Presidency, British India, situated on the Coromandel coast of the Bay of Bengal, 835 miles southwest of Calcutta and 640 miles southeast of Bombay; lat. 13° 4′ N., long. 80° 15′ E. (Map: India, D 7). It is the third city in size in India and has railroad and telegraphic communications by the main systems with the principal towns of the Empire, but although much has been done to improve its harbor facilities, it is no longer a port of call for the principal European lines of ocean steamers, owing to the insecurity of its harbor. The city, including the nine suburbs, covers an area of 27 square miles, extending along the coast for 9 miles and inland for nearly 4. Centrally situated on the shore is Fort St. George, strongly fortified and garrisoned by European and native troops and containing the council house, civil and military offices, and St. Mary's, the oldest English church in India, dating from 1678. Adjoining the fort on the north is the commercial district of Black Town (officially George Town, after the visit of the Prince of Wales in 1906), a low-lying, poorly built, and densely populated quarter, covering an area of a square mile, protected from inundation by a strong sea wall. Here are situated the mercantile establishments, the Bank of Madras, the post office, and the old High Court, now occupied by the customs offices, its tower with a modern installation serving as the lighthouse for the harbor, which extends along the larger portion of the water front of Black Town. To the south and rear of the fort is the Island, formed by the encircling Cooum River, containing barracks and forming an extensive military parade and recreation ground. It connects by bridges on the north with the People's Park, which consists of ornamental grounds with a considerable zoölogical collection, and on the west and south with the residential sections, where are situated the handsome Government House, the clubs, marine parade, the Chepauk Park and buildings, St. Andrew's (the Scottish kirk), the fine university buildings, and the native hospital. On the Mount Road, commanding a magnificent view of the city and its vicinity, is St. George's Cathedral, in Ionic style, containing several beautiful monuments by Chantry and Flaxman. Other noteworthy features are the new Law Court buildings in a Hindu-Saracenic style of architecture, opened in 1892, the new Law College, the Christian College buildings, Pachayyappa's College and hall, the memorial hall, the grand arsenal, with an interesting military museum, the observatory, founded in 1792, which gives standard time to all India, and several native mosques and temples. The southernmost extension of Madras is the old Portuguese town of St. Thomé, near the Adyar River, with the ancient Roman Catholic cathedral of St. Thomé. There are several charitable and benevolent institutions, and Madras is noted for its educational establishments, which include the university, founded in 1857, colleges of agriculture, of engineering, medicine, and law, a teachers' college, six missionary colleges, Victoria Technical Institute, a government school of arts, a valuable museum, libraries, zoölogical and botanical gardens, and literary and scientific institutions.

The city's affairs are administered, under a charter of 1884, by 32 commissioners, eight, including a salaried president, being appointed by the provincial authorities and 24 being elected by the ratepayers and certain public bodies. Madras has undergone much modern improvement; it has a good reservoir water supply, conveyed from a distance of 7 miles, and a sewage-farm disposal system, and is lighted by gas and electricity. Harbor works, commenced in 1876 and partially destroyed by a cyclone in 1881, were completed after much difficulty in 1896; they consist of two breakwaters, respectively 3907 and 3726 feet long, inclosing a large water area fronting Black Town. Passengers are now enabled to land in comfort without the former perils attendant on a passage through the notorious Madras surf, but during the cyclones of the monsoon periods the harbor is unsafe for large ships, which seek the open sea on receipt of meteorological warning. Numerous wrecks, many of historic interest, have occurred in the Madras roadstead. The foreign trade is on the increase. In 1898–99 the imports and exports of private merchandise amounted to £2,837,787 and £2,911,281, respectively; in 1903–04 they amounted to £4,076,895 and £3,411,948 respectively; in 1911–12, £6,241,353 and £4,656,843. The chief exports are cotton, rice, coffee, hides, and skins. Local traffic is facilitated by the Buckingham, Cochrane, and Cotton canals. Madras has some large cotton mills, but its industries are purely domestic and of no great magnitude. The United States is represented by a consul. The mean annual temperature is 82°; during the hot months the thermometer frequently registers 96° in the shade, but the heat is pleasantly tempered by "the doctor," a sea breeze so named by the residents, which sets in at noon and lasts till night. The seasons are distinctly marked by the monsoons, the northeast lasting from October to February and the southwest from May to October.

The population of Madras in 1871 was 367,552; in 1881, 405,848; in 1891, 452,518; in 1901, 509,346; in 1911, 518,660. Of the total population in 1901 about 79 per cent were Hindus, over 11 per cent Mohammedans, and about 8 per cent Christians. The chief vernacular is Tamil; Telugu is next in importance, being spoken by about one fifth of the people.

The Portuguese founded St. Thomé in 1504, but Madras dates from a grant of land made by the Raja of Chandragiri to a British subject in 1639 and the construction of Fort St. George. The place, known as Fort St. George, was raised to the rank of a presidency in 1653. By 1743 Madras had developed into the largest city of southern India; in 1746 it was captured by the French, but was restored in 1749 under the Treaty of Aix-la-Chapelle. In 1749 St. Thomé was annexed by the English. Madras was again besieged, but unsuccessfully, by the French in 1758–59.

MADRA′SAH (Ar., school, from *darasa*, to study). The name given by Mohammedans to their colleges or institutions of higher education. In the first centuries of the Hejira there were no separate buildings for educational purposes; elementary and advanced instruction were both given in the mosques themselves or in annexes, and were largely of a desultory and voluntary character. In the eleventh century Nizan el Molk, under the Sultan Alp Arslan, is said to have founded the first college or *madrasah*, and the custom spread rapidly to every part of the Mohammedan world. Each of the four orthodox sects established colleges in the principal cities for the teaching of its tenets. Those of Bagdad at once became famous, and soon after those of Cairo (under Saladin), of Damascus (where over 30 existed), of Cordova, Seville, Malaga, and Granada in Spain, and of many cities in north Africa (Fez, Kufa, etc.), Turkestan, and Persia (Ispahan, Shiraz). Later there are said to have been as many as 500 colleges in Constantinople.

Sometimes these colleges were of a general character, teaching the doctrines of all four orthodox sects, as regards theology and jurisprudence, with the related or propædeutic subjects of grammar, exegesis of the Koran, traditions, rhetoric, logic, ethics, as well as such subjects as pure literature, medicine, mathematics, physics, and philosophy. There was a regular staff attached to each, divided ordinarily into three classes: the *cadi* or judge, the *mudarris* or professor, and the *katib* or reader. They received a salary from the endowment of the college, which was administered by a body of trustees; such property was called *wakf*. A certain number of regular students were also supported from this endowment, both teachers and students living in the college buildings. Besides a large lecture hall and several smaller ones, a hospital and operating rooms, a library, dormitories, kitchen and refectory, there were large and small special buildings, particularly mausoleums and a mosque for religious devotions. Sometimes there were observatories and botanical gardens.

Hardly any large Mohammedan city is without several such madrasah groups of buildings, usually of the late mediæval period. For the study of architecture they are almost as important as the mosques (q.v.). In fact, they usually include both mosques and minarets, and sometimes the mosque forms the centre and key of the group of buildings. The magnificent so-called mosque of Sultan Hasan at Cairo (fourteenth century) is really a college with a mosque attached to it; so is that of Kalaûn. Others at Cairo are those of Khawand el Baraka, of Kaït Bey, of sultans Barkuk and Muayyed. That of El Azhar belongs to the greatest of all Moslem universities. If in these and many other cases the buildings of the college proper are subordinate to the mosque, there are others where it is not so. The madrasah of Sultan Hussein at Ispahan, built around an immense court, with a double gallery of arcades, is especially magnificent. The word as applied to Turkish institutions takes the Turkish form of *medress* or *medressé*.

MADRAS SYSTEM. See MONITORIAL SYSTEM.

MADRAZO, mä-drä′thō. A family of Spanish painters. The eldest, Don José de Madrazo (1781–1859), was born in Santander and studied under Ferro at the Madrid Academy, under David in Paris, and later at Rome. He was director of the Academy of San Fernando and exercised a decidedly deteriorating influence on the development of Spanish painting. His pictures, mostly historical, and painted in a dry, classical style, include several in the Madrid Gallery and one in the Quirinal Palace, Rome.

His son and pupil, Don Federigo (1815–94), born in Rome, studied also under Winterhalter in Paris, then returned to Spain, and in 1859 became professor in the Academy of Madrid. With his brother-in-law, Ochoa, he founded *El Artista* (1835). Madrazo's most typical canvases are the able and numerous portraits of Spanish nobles, especially of Queen Isabella, of Angel Saavedra, and of Campoamor. In his historical paintings, which are of less merit, he imitated Murillo's coloring and produced such pictures as "Godfrey de Bouillon Crowned King of Jerusalem" (Museum of Versailles) and "Maria Christina at the Bedside of Ferdinand VII." Among his later works were some excellent genre pictures, the chief being "The New Song," "The Cigarette," and "The Musical Matinée." He was court painter and curator of the Madrid Gallery and did much to revivify Spanish art.

Don Raimundo (1841–1920), the most gifted member of the family, was born in Rome, and studied with his father Don Federigo, at the Beaux-Arts, Paris, and under Cogniet. His portraits have exceptional dash, brilliancy, grace, and finish, and show excellent draftsmanship and able characterization. Fine examples are the Queen Regent of Spain; the Countess Pillet-Will; Mrs. Cornelius Vanderbilt, Mrs. Whitney, Miss Anne Morgan, Madame Madrazo, and Samuel P. Avery (Metropolitan Museum, New York). His genre paintings are no less brilliant in execution and color. He received a first-class medal at the Paris Exposition of 1878 for "The End of a Masked Ball" (purchased by W. H. Vanderbilt). Other typical works are: "Fête during Carnival" and "Girls at a Window," both in the Metropolitan Museum, New York; "A Lady with a Parrot" (W. A. Clark, New York); "Woman with a Guitar," "Déjeuner of the Infanta," and "Pierrette." He received many medals and was made a Commander of the Legion of Honor. He established himself in Paris. His brother Ricardo (1852–), born in Madrid, studied under his father and his brother-in-law Fortuny, and became well known as a portrait and genre painter.

MADRE DE DIOS, mä′drâ dâ dyôs (native name *Amaru-Mayu*). The principal tributary of the Beni River (q.v.) in South America. It rises in the Carabaya Range in the southeastern part of Peru, about 50 miles east of Cuzco. Thence it flows eastward for 900 miles through the almost unknown forest regions of La Montaña, crossing the extreme northern part of Bolivia almost parallel with the Brazilian boundary. At Rivera Alta it enters the Beni, about 150 miles from its confluence with the Mamoré. It was long an object of geographical conjectures, only its upper course being known until 1865, when it was explored by a party sent out by the London Geographical Society. It is a magnificent stream, over 500 yards wide at the Bolivian frontier and 1500 yards wide at its confluence with the Beni. It is as yet little used, but since 1881 the exploitation of rubber along its shores has been carried on.

MAD′REGAL. A West Indian name for one or two of the lesser species of amber fish (q.v.), as *Seriola fasciata* and *Seriola falcata.*

MAD′REPORE (from It. *madrepora*, mother-of-pearl, probably from *madre*, from Lat. *mater*, mother + Gk. *πόρος*, *poros*, passage, pore, or *πῶρος*, *pōros*, light friable stone). A large branching coral abounding on the reefs of Florida and other parts of the tropics in the Atlantic, Pacific, and Indian oceans. The most abundant species in the West Indies is *Madrepora cervicornis*, so called from its habit of growing in bushlike masses nearly 2 feet high and 3 to 4 feet in diameter, the separate spikes or branches resembling the antlers of a deer. It is the most abundant of the true reef-building corals. It grows up to the level of the sea, and then, becoming exposed at low water, the tips of the branches are often killed. It easily breaks when exposed to the waves, as it usually is, and its fragments form a large proportion of the coral sand, which becomes solidified into coral rock. See Coral, and accompanying Plates.

The madrepore is the most complex of all the corals. Its treelike form is due to multiplication of the smaller corallites by budding. A corallite is the individual polyp of the colony supported by its coral stock or skeleton. It is a perforate type of corals, all parts of the coral stock and connecting cœnenchym (formed by the calcification of the cœnosarc or inner layer of the polyp) being like a meshwork consisting of calcareous fibres arranged like basketwork, and traversed by a network of tubes, representing the cœnosarc and communicating with the other polyps of the colony. The madrepores do not live in water the winter temperature of which is under 60° F. They abound on the Bermuda Islands in the Atlantic, and as far north as southern Japan in the Pacific Ocean, while their southernmost limits are Rio de Janeiro and St. Helena in the Atlantic and Queensland and Easter Island in the Pacific Ocean. Thus they extend to about north and south latitude 30°.

Consult authorities cited under Coral, and particularly Saville Kent, *The Great Barrier Reef of Australia* (London, 1893), containing many illustrations from photographs of these and other reef corals.

MADRID′, *Sp. pron.* mȧ-drēᴅ′. The capital of Spain and of the Province of Madrid in New Castile. It is situated in lat. 40° 24′ N. and long. 3° 41′ W., nearly in the centre of the Kingdom, on a plateau 2100 feet above the sea, and on the left bank of the Manzanares, a small affluent of the Jarama, which latter flows into the Tagus (Map: Spain, D 2). The situation is unfavorable from almost every point of view. The surrounding plateau is treeless and bare and almost uninhabited, and the city is exposed alike to the scorching south winds and the fierce rays of the sun in summer and to the icy north winds from the snowclad Sierra de Guadarrama in winter; the extreme annual range of temperature sometimes reaches 100°. The clearness and dryness of the atmosphere, however, and the extensive plantations which have in the last half century grown up in the suburbs make the climatic conditions less unbearable.

The old city has the form of an oval contracted at the middle, and was surrounded by a wall which was razed in 1878, thus bringing the suburbs into the greater modern city, which is well provided with plazas, parks, and promenades. In the centre of the old city is the plaza called La Puerta del Sol, from the gate which stood there in mediæval times. This is the business centre and the terminus of all the street railways, and around it are the most prominent hotels and commercial houses. In its centre are a monumental fountain and a statue of Philip II. From here the principal streets of the city radiate in all directions. Westward run the Calle del Arenal and Calle Mayor, both leading into the large open place in which is the Royal Palace, and which in the north, in front of the palace, is laid out in the plantation called Plaza de Oriente. Here is the magnificent equestrian statue of Philip IV; it was designed by Velazquez and cast by Tacca. Farther west, between the palace and the river, are the royal gardens, and from these the Puente de Segovia and the Puente del Rey lead across the river into the large royal park of Casa de Campo. Eastward from the Puerta del Sol run the Calle de Alcalá and the Carrera de San Jerónimo into the broad and magnificent boulevard (Paseo) which runs north and south the entire length of the city and between it and the eastern suburbs. This is one of the finest promenades in the world, is shaded by four to six rows of trees, and ornamented by a number of fountains, statues, and other monuments, among which are an obelisk and an equestrian statue of Queen Isabella. The names of the boulevard, beginning at the south, are the Paseo del Prado, Salón del Prado, Paseo de Recoletos, and Paseo de la Castellana, and it terminates in the north at the Hippodrome. East of the Paseo del Prado is the Botanical Garden, and east of the Salón del Prado the Jardín del Buen Retiro; eastward of both and separated from them by the Calle de Alfonso XII is the large Retiro or Parque de Madrid; these parks are beautifully laid out with lakes and parterres, and ornamented with fountains and statues. Among the public monuments should be mentioned some of the old city gates which have been left standing as triumphal arches. The chief of these is the Puerta de Alcalá in the Plaza de la Independencia, an expansion of the Calle de Alcalá east of the Paseo. It was erected in 1778 in honor of Charles III, and is an imposing structure pierced by five gateways, the three in the middle being arched.

Madrid is distinctly of modern date, and it has none of the old architectural monuments boasted of by other Spanish cities. Foremost among the buildings stands the Royal Palace, on the site formerly occupied by a Moorish castle, which was renovated and used as a residence by Emperor Charles V and the monarchs of the Hapsburg dynasty. The modern palace was planned by Philip V, begun in 1738 and occupied in 1764. It is an imposing granite structure, built on a square plan with sides 470 feet long inclosing an inner court, while two projecting wings to the south inclose the Plaza de Armas. The uneven site is leveled by huge substructures of solid masonry. Above these are three basement stories, the fourth or principal floor being surrounded by a balustrade from which a series of Ionic and Doric columns reach to the roof. At the main entrance is a large *patio* containing statues of Roman emperors. The interior halls and salons are superbly decorated with frescoes, paintings, and statuary. Next to the palace, the finest building in the city is that of the National Library and Museum, situated on the Paseo de Recoletos. It is a new building, finished in 1892, and is regarded as one of the handsomest of its kind in Europe. It is a large rectangular structure with a wide flight of marble steps leading from the Paseo to the main entrance; in the interior is a large reading room 90 feet square and 60 feet high. Among other secular buildings might be mentioned the city hall and the buildings devoted to the departments of the government, especially that of the Ministry of War, which occupies the vast palace formerly the residence of the dukes of Alba, and the large and handsome building at the south of the Botanical Garden, which is occupied by the ministries of Public Works, Agriculture, Industries, and Education, and nearly opposite which is the new station of the Southern Railway. The two houses of the Cortes meet in separate buildings, the Senate occupying an old Augustinian convent which has been restored. The Bank of Spain and the Royal Exchange occupy new and monumental buildings. The most notable of the churches is probably that of San Francisco el Grande, built in the eighteenth century, and recently subjected to an extensive restoration. Its main body is circular, surmounted by a grand cupola, and with two lateral towers.

Foremost among the educational institutions of Madrid is the university with over 5000 students. (See MADRID, UNIVERSITY OF.) There are also a normal school, a veterinary school, schools of commerce, engineering, architecture, music and fine arts, and the astronomical observatory, an elegant and well-equipped building situated in the Parque de Madrid. Between the Parque and the Prado is the Botanical Garden, containing an immense wealth of flora as well as large herbaria and other collections. Madrid is rich in libraries and museums. The National Library, in its large new building, contained, in 1913, 650,000 volumes, about 30,000 manuscripts, a collection of 100,000 engravings and drawings, a fine archæological collection, and a museum of natural history. The library of the university contained, in 1913, 267,000 volumes, and the Marine Library has 26,383 volumes. The National Museum of Painting and Sculpture, occupying a fine large building on the Prado, has a collection of masterpieces rivaling those of the Louvre. Raphael, Titian, Rubens, etc., are well represented, and above all the painters of the Spanish School, Velazquez being here seen at his best. Another famous museum of Madrid is the Royal Armory, containing the richest and finest collection of arms in existence. Besides these are a number of minor museums. Madrid is the seat of various scientific and literary societies, chief among which are the Spanish Academy, similar in scope and purpose to the Académie Française, and the Historical, Anthropological, and Geographical societies.

Madrid has a score of theatres; the most prominent are the Teatro Real, facing the Royal Palace, the Teatro de Apolo, and the Teatro de la Comedia, which is one of the most popular. The Plaza de Toros, or bull ring, is a magnificent structure built in pure Moorish style and seating over 13,000 spectators. There are a number of large and well-equipped hospitals and asylums and a fine new model prison. The public works of the city are in general well developed, especially the electric street railways and gas and electric light; there is also a good system of street cleaning. The water supply, however, formerly noted for its abundance and purity, did not keep pace with the population. The old reservoir of the Lozoya canal (32 miles long) became inadequate, and two new reservoirs were constructed.

Formerly Madrid was conspicuous for its lack of industrial activity. Owing to the unfavorable situation, the cost of living was very high, and it was chiefly the fact of its being the capital, with the numerous train of officials, courtiers, and office seekers, that made it a lively and bustling town. But since the last decade of the nineteenth century its industries have developed remarkably. Among its factories the principal is the large national tobacco factory. There are manufactures of jewelry, leather articles, fans, umbrellas, musical instruments, chemicals, soaps, perfumes, drinks, and many other articles. The commerce of the town is active. It is the general railroad centre for the entire country, as well as the principal storehouse for the inland provinces. There are two large and a number of smaller markets, several prominent banks and commercial and insurance companies, an exchange, and a chamber of commerce. The population of the municipality in 1877 was 395,871; in 1900, 539,835; in 1910 (census of December 31), 599,807; est. pop., 1919, 608,793.

Nothing is known of Madrid previous to the Saracen occupation. In the tenth century it appears as a small fortified outpost under the name of Majerit (Majoritum). It was taken from the Moors by Alfonso VI in 1083, but was recaptured in 1109 and held for a short time by the Almoravides. The Cortes met in Madrid for the first time in 1329, but it was not until 1560 that the city was made the permanent capital of Spain by Philip II. On Jan. 14, 1526, a treaty was concluded at Madrid between Charles V and Francis I, who was then a prisoner in the hands of his rival. Francis, having secured his liberty, violated the terms of the treaty and renewed the struggle with Charles. On May 2, 1808, the citizens of Madrid gave the signal for the War of Independence, by rising in revolt against the French general, Murat. Over 1500 of the patriots were killed in a battle on the Prado, where a monument now commemorates them. For this brave attempt the city received the title of *Muy Heróica Villa*. Curiously enough, though it is the largest town in the Kingdom, it has never received the title of *ciudad*, or city.

Consult: Amador de los Ríos and Rada y Delgado, *Historia de la villa y corte de Madrid* (4 vols., Madrid, 1860–64); Valverde y Alvarez, *La capital de España* (ib., 1883); Williams, *Toledo and Madrid: Their Records and Romances* (London, 1903); A. F. Calvert, *Madrid: An Historical Description and Handbook of the Spanish Capital* (New York, 1909); J. C. Van Dyke, *Madrid: Critical Notes on the Prado* (ib., 1914).

MADRID, UNIVERSITY OF. A Spanish university which originated in the foundation of the College of Doña María of Aragon by Alonzo Orozco in 1590, perhaps on an older foundation of 1508. The Hapsburg kings set up schools for mathematics and science in the Alcázar in the sixteenth and seventeenth centuries, and in 1786 the College of San Carlos was opened in Madrid for the study of medicine and surgery. After many plans to move the University of Alcalá to Madrid, the transfer was finally accomplished in 1836–37, and from this removal the foundation of the University of Madrid may be said to date. It is now one of the largest of European universities, and the leading institution of Spain. United with it is the great preparatory school of San Isidorio, founded by Philip IV, and reconstituted by Charles III in 1770. The University of Madrid has a budget of more than 1,000,000 pesetas, and it had in 1913 an attendance of 5675 students, the great majority of whom are in the faculties of law and medicine. The library has over 267,000 volumes and about 5500 manuscripts. The University of Madrid includes museums, clinics, collections, and an observatory.

MADRID, JOSÉ FERNÁNDEZ-. See FERNÁNDEZ-MADRID, JOSÉ.

MAD'RIGAL (Fr. *madrigal*, from It. *madrigale*, OIt. *madriale*, *mandriale*, ditty, Lat. *mandra*, from Gk. *μάνδρα*, flock; the etymology *matricalem* from *matrem*, mother, has also been suggested). A short lyrical poem, adapted to the quaint and terse expression of some pleasant thought, generally on the subject of love. Though somewhat varied in form, it usually consists of from six to 13 short iambic lines constructed upon three rhymes. Developed in Provence, it became very popular in Italy, where the best writers of madrigals are Petrarch and Tasso; among the French, Clement Marot; among the Germans, Hagedorn, Voss, Goethe, and Schlegel; and among the English, William Drummond, Lodge, Withers, Carew, and Suckling. The name madrigal is also applied to a form of vocal composition which during the sixteenth century occupied a position very similar to that of the *Kunstlied* (art song) of to-day. It was set generally for five voices, but madrigals for three, four, six, and eight voices are also found, usually without accompaniment, and in counterpoint. The texts were generally of an erotic character, as the first musical settings for madrigals were the compositions of troubadours, but the form was later much used by ecclesiastical musicians. The madrigal differed from the more popular frottola and villanella in its elaborate contrapuntal workmanship. Dante's friend Casella is reputed to have been the first notable composer of this form in Italy. But the real father of the madrigal is Adrian Willaert (1480–1562), who was born in Flanders, but went to Italy and there developed this form from the then existing frottola. As perfected by this master the madrigal, usually developed from the theme of a plain song or popular melody, soon found its way beyond Italy. In 1538 Arcadelt published in Venice a book of madrigals, in the form already established by Willaert. It was received with enthusiasm. The Flemish school which then developed was a flourishing one and in turn influenced the Italian madrigal, which helped to develop the opera, for after the establishment of the "monodic style" popular madrigals were arranged for a solo voice with accompaniment of the lute or some other instrument. In this way the madrigal became an important factor in the propagation of the new monody. The precursor of the Florentine *dramma per musica* (see MONODY) was in fact nothing else than a succession of monodic melodies loosely strung together. After the establishment of monody, madrigals gradually fell into disuse, but not before the great Roman school under Palestrina and the Venetian school with its Gabriellis and Costanzo Porta had produced interesting examples of this form. Madrigals were introduced early into England, but the first English collection, *Musica Transalpina*, edited by N. Yonge (1588), was made up mainly from translations of the Italian. Previously, however, in 1530, a collection of polyphonic songs had been published by Wynkyn de Worde. There are now extant more than 1000 madrigals composed by about 100 different musicians of the seventeenth century. Among the most distinguished English composers in this form are William Byrd (the earliest), John Wilbye, John Dowland, Thomas Morley, and Orlando Gibbons. In 1604–10 the famous collection, "The Triumphs of Orcana," was published and in 1741 the Madrigal Society of London was founded. In the latter part of the seventeenth century few madrigals were sung and fewer composed. Part songs were still in favor, but they lacked counterpoint, the peculiar characteristic of the madrigal, which for nearly two centuries had held its place in musical performances. Consult: Karl Vossler, *Das deutsche Madrigal* (Weimar, 1898); Cox, *English Madrigals in the Time of Shakespeare* (London, 1899); S. Tomaselli, *Il madrigale nella seconda meta del secolo XVI* (Belluno, 1904); J. A. Fuller-Maitland, "A Waning Glory of England, the Madrigal," in *Nineteenth Century and After*, vol. lvii (London, 1905); Gaetano Cesari, *Le origini del madrigale cinquecentesco* (Turin, 1912).

MADROÑA, mȧ-drō′nyȧ. A California tree. See Arbutus.

MADSEN, mȧd′sĕn, Thorwald Johannes Marius (1870–). A Danish bacteriologist. He was born in Copenhagen, the son of V. H. O. Madsen, a major general who was Danish Minister of War in 1901. Educated at the University of Copenhagen, he was assistant in the university bacteriological laboratory (1894–1902) and after eight years in the State Serum Institute at Copenhagen became its director in 1910 and adviser in bacteriology and epidemiology to the Department of Health. He made special studies on active and passive immunization and on toxins and antitoxins, holding (with Arrhenius and against Ehrlich) that the chemical combination of toxin and antitoxin was a very loose one, in *Physical Chemistry applied to the Study of Toxins and Antitoxins* (1902). He edited the *Contributions de l'institut sérothérapeutique de l'état danois*.

MAD TOM. Any of several small catfish of the genus *Schilbeodes*, common throughout the fresh waters of the Eastern United States, especially southward. They have elongate bodies and very thick skins, and have habits similar to those of darters, "lying on the bottom among rocks and weeds and delighting in small, rocky brooks." The best-known species is *Schilbeodes insignis*, which reaches a length of nearly a foot; it is dark brown, somewhat mottled, and all the fins are broadly dark-edged. Another much mottled form is *Schilbeodes miurus*. These catfish have large poison glands, and a wound from the pectoral spine is painful, though not serious. See Catfish, and Plate of Catfish.

MADURA, mȧ-dōō′rȧ. The capital of a district in Madras, British India, the ancient capital of the Pandyan Kingdom, 270 miles (344 by rail) southwest of Madras (Map: India, C 8). It is celebrated for some of the finest examples of Hindu architecture in existence. It has wide and regular streets and large market places, and until recently was surrounded by a double wall with 72 towers and an encircling ditch from 60 to 70 feet wide; the dwelling houses, however, are poor. The Temple of Minakshi or Fish Mother, in the centre of the city, is one of the finest Dravidian buildings in India. It is said to have been partially destroyed in the flood of Menu, and to have been rebuilt by Sekhara Pandyan in the second or third century; to have been nearly destroyed during the second Mohammedan conquest in the fourteenth century, and renewed by Viswanatha Nayak. Its present splendor is due to Tirumulla Nayak, the last Rajah, who reigned 1622–62. The outer wall of the temple is a parallelogram of 847 by 729 feet, within which are 50 buildings devoted to the various purposes of the temple worship. The wall is of granite with a parapet of brick and is 37 feet high. The main entrances are by four *gopuras*, or gateways, 30 feet high, through pyramidical towers 50 or 60 feet wide at the base which rise in 11 stories to the height of 150 feet and are entirely covered with the most intricate carvings of gods and heroes of mythology, all painted and gilded. One choultry, or rest house, within the inclosure, built by Tirumulla Nayak, is 332 feet by 105, the roof supported by 162 columns, many of them wrought from a single stone. Fifty-four of these columns are 30 feet high, of two stones fitted face to face so as to look like one solid block 4½ feet thick, carved on all sides with life-size figures in full relief or in bas-relief. This hall is said to have cost $5,000,000. The granite roof in the Sahasrastambha Mandapam, or Hall of One Thousand Pillars, is supported in reality by 997 columns, and the columns in the whole temple number 10,000. A palace built by Tirumulla Nayak has been restored and is an edifice of considerable magnificence. Madura was the political and religious capital of south India from the earliest time. It is the Modura of Ptolemy, and in the time of Augustus its King sent ambassadors to Rome. Early in the Christian era a college was founded here for the cultivation of Tamil literature, and was distinguished for the learning of its professors. The care taken to preserve the purity of the language is in evidence to this day. The last sovereign, Queen Menakshi Amman, was dethroned by Chunder Sahib in 1736; from 1740 to 1760 the city was repeatedly besieged. A Roman Catholic mission, established here early in the seventeenth century, flourished until the English occupation. In 1837 it was reëstablished and is a prosperous institution. An American Protestant mission, to which a hospital is attached, was established in 1834. Two colleges and three schools receive state aid, and there are several literary institutes. Cotton and coffee mills and cigar factories are the chief industrial establishments, supplying a domestic trade. Pop., 1891, 87,428; 1901, 105,984; 1911, 134,130.

MADURA. An island of the Malay Archipelago, belonging to Holland, and separated by a narrow strait from the northeast coast of Java (Map: East Indies, D 7). Its area is 1726 square miles, including a number of small dependent islands, 2090 square miles; it is mountainous, with a not very fertile and poorly cultivated soil. Cattle raising is the chief occupation of the inhabitants. The production of salt is an important industry, but is entirely in the hands of the government; petroleum is also found. The island is administered by a Dutch Resident, subject to the general government of Java. The capital is Pamekasan, with a population (1905) of 8407, and the largest city is Sumenep (pop., 22,110). The population of the island, with its minor dependencies, was, in 1905, 1,843,601, of whom 621 were Europeans, 4734 Chinese, 1873 other foreigners, and the rest natives professing Mohammedanism. The natives of Madura resemble closely the Javanese proper, with whom they are allied linguistically and somatically. The Madurese are stronger and more active than the Javanese.

MADURA FOOT, or Mycetoma. This is also known as the fungus disease of India and is caused by invasion of the tissues of the foot by a vegetable parasitic fungus, *Streptothrix mycetoma*. The disease is localized in the foot, which becomes studded with cysts and open sores and sinuses which discharge an oily, thin, purulent fluid having an offensive odor. The foot becomes swollen and œdematous. In the early stages of the disease removal of the diseased tissue by scraping or excision may bring about a cure, but as a rule amputation is the only remedy. Consult Osler, *Modern Medicine* (New York, 1914).

MADVIG, mäd′vĭg, Johan Nikolai (1804–86). A Danish classical scholar, born at Svanike, in the island of Bornholm, Aug. 7, 1804. He was educated at the University of Copenhagen and obtained there the professorship of the Latin language and literature when he was only 25 years of age. Although his life was chiefly devoted to philological studies and to the careful editing of classical works, he held very important official positions in Denmark, where he was Minister of Public Worship from 1848 to 1852 and Director of Public Instruction in 1852. He was repeatedly elected to the National Legislature, was several times president of the Folkething, and was leader of the National Liberal party. He published a *Glance at the Constitutions of Antiquity;* an admirable edition of Cicero, *De Finibus* (1839); a *Latin Grammar for Schools* (1841, 1857, 1867; translated into English by Woods, then, after five editions in England, by Thacher, Boston, 1888); *Greek Syntax* (1846); *Adversaria Critica ad Scriptores Græcos et Latinos* (1871–73); *The Creation, Development, and Life of Language; Opuscula Academica* (1834–42); *Emendationes Livianæ* (1860, 1877); a text of Livy (1861–66); *Kleine philologische Schriften* (1875); and other works. Madvig exercised great influence by his writings upon both German and American scholarship, especially by his Latin Grammar and by his critical observations on various Latin authors, especially Cicero and Livy. He did much to further textual criticism (q.v.) by insisting that manuscripts of an author were to be valued according to their relation to the archetype of that author. His last works were a dissertation on *The Constitution of the Roman State* (1882) and an *Autobiography* which appeared in 1887, the year following his death, which occurred Dec. 12, 1886. Consult Henry Nettleship, *Lectures and Essays, Second Series*, 1–23 (Oxford, 1895), and J. E. Sandys, *A History of Classical Scholarship*, vol. iii (Cambridge, 1908).

MAD WORLD, My Masters, A. 1. A merry dialogue between two travelers by Nicholas Breton (1603). 2. A play by Middleton (1608), a vivacious comedy of a young scamp and an old grandfather. This was partly adapted by Mrs. Aphra Behn in her *City Heiress* (1682), and used by Charles Johnson in *Country Lasses* (1715).

MÆAN′DER (Lat., from Gk. *Μαίανδρος*, *Maiandros*, now called Menderes). The ancient name of a river of Asia Minor, rising near Celænæ in Phrygia and flowing in a southwest direction into the Icarian Sea at Miletus (Map: Greece, Ancient, F 3). It was famous in classic times for its numerous windings, and thus gave its name to the well-known and beautiful patterns known as *meanders*, so common in Greek ornamentation. Its course is 240 miles, during which it receives many tributaries. It is a narrow and deep stream, but frequently overflows its banks, and by means of alluvial deposits has extended its channel considerably. It is navigable for small vessels only.

MÆCENAS, mē̇-sē′nȧs, Gaius Cilnius. A Roman statesman, celebrated for his skill as administrator and diplomat, and even more for his patronage of letters. He was born between 73 and 63 B.C., perhaps at Arretium. His family was of Etruscan origin and claimed royal descent. He received an excellent education and was familiar with Greek and Roman literature. He first appeared in public life after the assassination of Julius Cæsar (44 B.C.), as the friend and adviser of Octavian, about 40 B.C. He had, it is clear, a talent for private diplomacy and was employed mainly in that capacity. He "arranged" a marriage between Octavian and Scribonia, made up (temporarily) the differences between Octavian and Antony, and brought about the peace of Brundisium (40 B.C.). Another important mission, in which he was mediator between Octavian and Antony, either in the fall of 38 or in the spring of 37, is alluded to by Horace in his famous account of his journey to Brundisium (*Sermones*, i, 5). In 36 B.C. he was in Sicily, helping Octavian, as usual. Five years later, when the latter was fighting the decisive battle of Actium with his rival Antony and Cleopatra, Mæcenas proved himself a vigilant governor of Rome by crushing a conspiracy of the younger Lepidus and thereby preventing a second civil war. When Octavian became Emperor under the title of Augustus (a step which he is said to have taken by the advice of Mæcenas, who was profoundly impressed with the necessity of a strong government to repress the anarchic elements of the period), Mæcenas was appointed administrator of all Italy. The nature and the extent of his official power are not very precisely understood, but it was undoubtedly great, though the influence and authority of Mæcenas are to be estimated rather from his intimacy with the Emperor than from his mere position as a public official. This intimacy continued uninterrupted for many years; but some time before 16 B.C. it was ruptured, from causes which cannot now be ascertained. No enmity, however, ensued. Mæcenas was a thoroughly sincere Imperialist. He had a belief in the value of an established government; and, when he found that he no longer retained the confidence of his sovereign, he did not lapse into a conspirator, but, as a modern minister might do, retired into the obscurity of private life. Literature and the society of literary men now occupied all his time. He was immensely rich, and kept an open table for men of parts at his fine house on the Esquiline Hill. His patronage of men of letters was due to his keen-sighted vision of the extent to which men of letters might make the new order of things, represented by the personal government of Octavian, palatable to the better classes. Mæcenas' relations with Horace (q.v.) especially were of the most cordial nature and equally honorable to both. It was he that gave to the poet the famous Sabine farm of which Horace sings so exquisitely in his *Odes*. It was he, too, that requested Vergil to write his *Georgics*. The poet Propertius was also one of Mæcenas' more intimate friends. As far as personal morality went, Mæcenas was a thorough pagan; he dressed effeminately, had a passion for theatrical entertainments, and gave great attention to cookery and gardening. It does not surprise us to find that he was a valetudinarian and a hypochondriac. He died childless in 8 B.C. Consult: for the preserved fragments of his verses, Baehrens, *Fragmenta Poetarum Romanorum* (Leipzig, 1886), and Harder, *Fragmenta des Mäcenas* (Berlin, 1889); also: V. Gardthausen, *Augustus und seine Zeit*, vol. i (Leipzig, 1891); W. Y. Sellar, *Horace and the Elegiac Poets* (Oxford, 1892); Charles Knapp, *Vergil*, Introduction (Chicago, 1901); Martin Schanz, *Geschichte der römischen Litteratur*, vol. ii, part i (3d ed., Munich, 1911).

MÆCENAS, Gardens of (Lat. *Horti Mæcenatiani* or *Horti Mæcenatis*). A magnificent pleasure ground laid out under Augustus by his minister Mæcenas (q.v.), who planned the work in order to do away with the pestilential condition of the popular cemetery on the Esquiline Hill (q.v.). Mæcenas covered the whole district, outside the Agger of Servius, north and south of the Porta Esquilina, with a layer of pure earth 20 to 25 feet deep and made the new ground into a garden. The effect on the city's health was marked, and is celebrated by Horace in *Sermones*, i, 8 (see notes in editions of Horace).

In the gardens were a palace and a tower, from which, according to Suetonius, Nero watched the burning of the city in 64. The extant remains consist of some rooms paved with mosaic, and a fine large building on the Via Merulana, once called an auditorium, but probably a conservatory. This is a hall, half underground, and has seven curved steps in the apse, arranged like the steps or seats of a theatre. Each wall is pierced by six niches, once covered with finely executed landscapes, which have now faded away. Many works of art, in great part portrait busts, have been found on the site of the gardens, and are preserved in the Conservatory Museum. Consult R. A. Lanciani, *Ancient Rome in the Light of Recent Discoveries*, pp. 65–67 (Boston, 1889), and S. B. Platner, *The Topography and Monuments of Ancient Rome* (2d ed., Boston, 1911), on p. 465 of which is a photograph of the "auditorium."

MAELAR, mā′lär. A lake of Sweden. See Mälar.

MÆLDUNE, mäl′dōōn. See Maildun.

MAELSTROM, mäl′strom. See Malström.

MÆ′NADS (Gk. *Μαινάδες*, *Mainades*, from *μαίνεσθαι*, *mainesthai*, to rave). A name given to the Bacchantes (q.v.), from their frenzied state in the worship of Dionysus. See Bacchæ; Bacchus.

MÆONIDES, mê-ŏn′ĭ-dēz, or **MÆONIAN SWAN**. A name given to Homer on the basis of the story that he was born at Smyrna in Lydia (q.v.), once called Mæonia.

MÆO′TIS PA′LUS. An ancient name of the Sea of Azov, also called Cimmerium Mare and Bosporicum Mare.

MAERCKER, mĕr′kĕr, Maximilian (1842–1901). A German agricultural chemist, born at Kalbe-an-der-Saale. He studied at Greifswald and Tübingen, in 1866 was appointed assistant at the Brunswick agricultural experiment station, in 1867 at that of Weende-Göttingen. In 1871 he became director of the experiment station of the Central Agricultural Union for the Province of Saxony at Halle, and in 1872 professor of agricultural chemistry in the university. He conducted extensive experiments on the value and use of fertilizers for all kinds of farm crops, the culture of various crops, and the feeding of live stock; gave much attention to the improvement of the sugar beet and its culture; and was an authority on alcohol manufacture and the distilling industry, his *Handbuch des Spiritusfabrikation* (6th ed., 1894) being a standard work. In 1893, under commission from the Ministry for Agriculture, he studied American agricultural methods and institutions as displayed at the Chicago Exposition and prepared a report, *Amerikanische Landwirtschaft und landwirtschaftliches Versuchs- und Unterrichtswesen* (1905). In this he recommended the establishment of an experimental farm of the American type, and such a farm, the first in Germany, was instituted under his direction in 1895 at Lauchstädt, near Halle. A monument to him was erected in Halle in 1905. He also wrote, besides contributions to periodicals, *Die Kalisalze und ihre Anwendung in der Landwirtschaft* (1880); *Die Kalidungung in ihrem Wert für die Erhebung und Verbilligung der landwirtschaftlichen Produktions* (2d ed., 1894); and a long list of reports and addresses. Consult Behrend-Hohenheim, "Max Maercker, Ein Rückblick," in the *Landwirtschaftliche Jahrbücher*, vol. xxxi (Berlin, 1902).

MAERLANT, mär′lȧnt, Jacob de Coster van (c.1235–c.1291). A Flemish poet, called, not unjustly, the father of Dutch literature, for in him are combined its learning, its practical sense, its didactic zeal, and its aversion to chivalrous ideals. He was born near Bruges and died at Damme, near Bruges. At first Maerlant yielded to the universal vogue of the romance of chivalry. He was parish clerk at Maerlant when he adapted from the French an *Alexander* (1257; printed 1860–61 and 1882) and a *History of Troy* (1264, printed in part, 1874 and 1891). He also rendered into Dutch a *History of the Graal* and the *Book of Merlin* (5th ed., 1883). Then, moving to Damme and becoming chancellery clerk, he first turned his mind to present social conditions in three strophic poems, called the *First*, *Second*, and *Third Martin* (printed 1496 and 1880), and then began the series of didactic works with which his name is especially associated by *The Secret of Secrets*, a treatise on government (printed 1838 and 1844). *Flowers of Nature* (printed 1878) followed, an adaptation of Cantimpré's Latin *De Rerum Natura*. Then came the most famous of his books, *The Rhymed Bible*, based on the *Scholastica* of Comestor with an addition from Josephus on the fall of Jerusalem (1271; printed 1858–69), a work that brought him into conflict with some of the clergy, though the Franciscans soon after employed him to translate into Dutch St. Bonaventure's *Life of Saint Francis* (printed 1848). He then (1283) began his most extensive work, a popularization of the *Mirror of History* by

Vincent of Beauvais (printed 1857–63), which he did not live to finish. He wrote also in his last years a fine crusader's song, *Of the Land Over-Sea.* Maerlant was in literature the representative of the national element among his countrymen against French influence, brought in by the court and nobility. All his writings were in verse. Consult: Serrure, *J. van Maerlant, en zijne werken* (Ghent, 1867); J. te Winkel, *Maerlants Werken, etc.* (Leyden, 1877; 2d ed., Ghent, 1892), and G. Kalff, *Geschiedenis der nederlandsche Letterkunde,* part i (Leyden, 1887); J. P. W. Crawford, "The Catalan Mascarón, and an Episode in Jacob van Maerlant's Merlijn," in *Modern Language Association, Publication,* vol. xxvi (Cambridge, Mass., 1911).

MAES, or **MAAS,** mäs, Nicolas (1632–93). A Dutch genre and portrait painter. He was born at Dordrecht and was a pupil of Rembrandt. The genre paintings of his early period, executed in the manner of Rembrandt, are real masterpieces. Among these are "The Eavesdropper" (Six Gallery, Amsterdam); "Old Woman Spinning"; "Girl at a Window" and "Grace" (Rijks-Museum, Amsterdam); the "Cradle," "Dutch Housewife," and "Idle Servant" (National Gallery, London); "Killing Pigs" and a "Bishop Reading" (Berlin Museum); and "Saying Grace" (Louvre). Maes also painted a number of religious pictures. A good example is "Hagar's Farewell," which has long been labeled a Rembrandt (collection of the Earl of Denbigh). During his residence at Antwerp (1660–65) he adopted a smooth and finished style, showing the influence of Van Dyck. His work became uninteresting and spiritless, as may be seen from his later portraits at Amsterdam and Rotterdam. In 1906 the Metropolitan Museum, New York, acquired an excellent example of Maes's work, the portrait of an elderly woman in black, and in 1914 (in the Altman collection) "Young Girl Peeling an Apple." Consult Bode, *Great Masters of Dutch and Flemish Painting* (Berlin, 1906; Eng. trans., 1909).

MAESHOWE, mās′hou. An artificial tumulus, situated on the island of Orkney, about 9 miles west of Kirkwall and a little more than a mile from the standing stones of Stennis (q.v.).

MAESTEG, mīs′tĕg. A town in Glamorganshire, Wales, 8 miles southeast of Neath. It is engaged chiefly in coal mining. Pop., 1901, 15,000; 1911, 24,977.

MAESTOSO, mä′ĕ-stō′sȯ. An Italian term in music, meaning 'with majesty or dignity.'

MAESTRAL. See Mistral.

MAESTRICHT, or **MAASTRICHT,** mäs′trĭKt (Lat., *Trajectum ad Mosam,* i.e., Meuse crossing). The capital of the Province of Limburg, Netherlands. It is situated 19 miles north of Liége, Belgium, on the left bank of the Meuse, over which a stone bridge, built in 1683, leads to the suburb of Wijk, where the railroad station is (Map: Netherlands, D 4). It is well built and has several interesting buildings. On the great market place stands the beautiful town hall, with its clock tower, dating from 1659 to 1664. The building contains several Dutch paintings and fine tapestries. The Hoofdkerk, or church of St. Servatius, built partly in the Romanesque, partly in the Gothic style, is the oldest church in the Netherlands. It has an altarpiece by Van Dyck. Before the high altar is the reliquary of St. Servatius, nearly 6 feet in length by 2½ high, built in the form of a church of gilded and enameled copper and filigree work. It dates from the twelfth century and is unique. The church treasury also contains some interesting antiquities and fourth-century objects belonging to Servatius, including a key of electrum. The town has a number of other churches of singular interest to the archæologist. The town has a library with the provincial archives, an athenæum, and several technical schools. Probably the most remarkable attraction of the neighborhood is the Petersburg sandstone quarries, worked from Roman times and consisting of a labyrinth of subterranean passages extending over a vast area. The chief industries of the town consist of brandy making and beer brewing, together with the manufacture of tobacco and cigars, woolen goods, glass, earthernware, soap, paper, and arms.

Maestricht was early the seat of a bishop and was in the latter part of the Middle Ages in the joint possession of the dukes of Brabant and the bishops of Liége. Owing to its strategical position on the frontier, it has often borne the brunt of war. In 1579 it was captured and sacked by the Spaniards under the Duke of Parma, and thousands of its inhabitants were massacred. It was captured by Prince Frederick Henry of Orange in 1632, and in 1673, 1748, and 1794 by the French. In the Belgian revolution of 1830 it was almost the only town along the frontier which withstood the attack of the insurgents. Its fortifications have been razed, but its garrison is still maintained. Pop., 1900, 34,220; 1912, 38,611.

MAESTRICHT BEDS. An important formation of soft yellowish limestone occurring at Maestricht in Holland, abounding in the remains of corals and Bryozoa, sometimes, indeed, entirely made up of them. The fossils are peculiar and quite distinct from Tertiary species. It overlies the chalk stratigraphically.

MAESTRO, mȧ-ĕs′trȯ (It., master). An Italian term, used in the same general sense as the English word "master." The *maestro al cembalo* was the conductor of opera in Italy during the first half of the nineteenth century. He did not direct by means of a bâton, but played the cembalo (piano) and directed very much as the pianist does to-day in a performance of chamber music for piano and strings. Rossini, Bellini, Donizetti, all directed their works from the cembalo. (See Conductor.) *Maestro di capella* is the conductor and trainer of a choir; *maestro dei putti,* the conductor of the boys' choir at St. Peter's in Rome.

MAETERLINCK, mä′tĕr-lĭnk, *Fr. pron.* mȧ′tĕr′lăN′, Georgette Leblanc (?–). The wife of Maurice Maeterlinck and sister of Maurice Leblanc (qq.v.). She was born at Rouen and became well known as a tragic and emotional actress. Before her marriage, in 1901, she had been a member of the Comédie Française. She created the parts of Charlotte Corday, Monna Vanna, Télaire in the *Castor et Pollux* of Rameau, and Marguerite in Boito's *Mefistofele.* Subsequently she played in a number of her husband's dramas. When a notable performance of *Macbeth* was given at the Maeterlinck home, the historic Abbaye de Saint-Wandrille, Madame Maeterlinck performed the part of Lady Macbeth. A. Teixeira de Mattos made translations of her writings under the titles *The Blue Bird for Children* (1913); *The Girl who Found the Blue Bird* (Helen Keller)

(1914); *The Choice of Life* (1914)—all published in New York.

MAETERLINCK, Maurice (1862–). A Belgian poet, born Aug. 29, 1862, in Ghent. He studied some time in a Jesuit school, then pursued philosophy and law. In 1887 he became a barrister, but in 1896 he settled as a man of letters in Paris. He first wrote *Serres chaudes* (1889) and added to these verses *Douze chansons* (1896). One of these betters an inspiration which Rossetti, in "An Old Song Ended," had got from Ophelia's song in *Hamlet* (Act. iv, Scene 1). His plays—*La princesse Maleine* (1889); *Les aveugles* (1890); *L'Intruse* (1890); *Les sept princesses* (1891); *Pelléas et Mélisande* (1892); *Alladine et Palomides: Intérieur* (1894); *Mort de Tintagiles* (1894); *Aglavaine et Sélysette* (1896); *Sœur Béatrice* and *Ariane et Barbebleue* (1899); *Monna Vanna* (1902); *Joyzelle* (1903); *Le Miracle de St. Antoine* (1905); *L'Oiseau Bleu* (1909), played in the United States as *The Blue Bird; Marie Magdeleine* (1910)—are dramatic in form, but for the most part their mystic quality greatly lessens their dramatic effect. Maeterlinck's spirit is imbued in mysteries. He is symbolistic, though by no means the earliest modern symbolist. He broods over death and sees life with poetic rather than accurately analytic vision. He lives in a dreamy atmosphere, and the puppets in his dramas are rather such stuff as dreams are made of than men and women. Without passion or will, enthralled by Maeterlinck's spirituality, they wander blindly. They are either ghosts or marionettes. It is natural, therefore, that Maeterlinck should appeal not to the public in general, but rather to a special school of admirers who have studied his idiosyncrasies. To the thinking of many critics Maeterlinck is best in his essays. *Le trésor des humbles* (1896), *La sagesse et la destinée* (1898), and Maeterlinck's *Introduction* to his translation of Ruysbroeck's *L'Ornement des noces spirituelles* express Maeterlinck's mystic philosophy. *La vie des abeilles*, translated by Sutro (New York, 1902), is an artist's study of bee life. Here Maeterlinck's sensuous outlook on life, his painter's vision, has no need of psychology; for he is dealing with throngs rather than with individuals, yet there is in his setting forth of the bee's activity, intelligence, instinct, and beauty a precision which evidences first-hand knowledge. Later studies are *Le temple enseveli* (1902); *Le double jardin* (1904); *Mon chien* (1906), which again reveals sympathetic intuition into animal life; *L'intelligence des fleurs* (1907); and *La mort* (1913). His dramas, which were translated by Richard Hovey (New York, 1896), show the influence of the Elizabethan playwrights. Their weird unreality suggests such writers as Villiers de l'Isle-Adam and De Quincey, Rossetti, and Poe, as well as mystic writers of bygone ages. A great many of Maeterlinck's later dramas and essays have been translated by Alexander Teixeira de Mattos and published in New York. In 1911 Maeterlinck was awarded the Nobel prize for literature, and in 1915 he received from the Société des Gens de Lettres one of the two prizes established by Prince Bonaparte. Consult: W. L. Courtney, *The Development of M. Maeterlinck* (London, 1904); M. J. Moses, *Maurice Maeterlinck: A Study* (New York, 1911); E. Thomas, *Maurice Maeterlinck* (ib., 1911); J. Bethell, *The Life and Works of Maurice Maeterlinck* (ib., 1913); Archibald Henderson, *European Dramatists* (Cincinnati, 1913); E. E. Slosson, *Major Prophets of To-Day* (Boston, 1914); G. F. Sturgis, *The Psychology of Maeterlinck as Shown in his Dramas* (ib., 1914).

MÆVIUS, mē′vĭ-ŭs. See Bavius and Mævius.

MAFEKING, măf′ĕ-kĭng. A town of British South Africa, the seat of the administration of the Bechuanaland Protectorate, situated near the west frontier of the Transvaal Province, 870 miles northeast of Cape Town and 4194 feet above sea level (Map: Cape of Good Hope, G 5). It became famous during the Boer-British War of 1899–1902 as the place where the British, under Sir Robert Baden-Powell, were besieged by the Boers under Cronje from Oct. 11, 1899, to May 18, 1900. Mafeking is the headquarters of the railroad system between Kimberly and Bulawayo and has large railroad workshops. There are three considerable gold fields within a radius of 30 miles of the town, which is the chief trading and distributing centre for Bechuanaland and the western Transvaal. The chief buildings are the town hall (1904), the Masonic Temple, the hospital, and the Anglican Memorial Church. Pop., 1911, 1404.

MAFFEI, mȧf-fā′ē, Andrea (1800–85). An Italian poet, born at Riva di Trento. He became known by his translations from German and English, among these being the complete dramatic works of Schiller (1844) and Milton's *Paradise Lost* (1857). He also translated several poems of Byron and Moore, some of Goethe's works, and Shakespeare's *Macbeth*, *Othello*, and *The Tempest* (1869). His original volumes are *Dal Benaco* (1854) and a larger collection of poetry, *Versi editi ed inediti* (1858–60). Consult Benvenuti, *A. Maffei, poeta originale e traduttore* (Trent, 1911).

MAFFEI, Giovanni Pietro (1536–1603). An Italian Jesuit historian, born in Bergamo. He was professor of eloquence at Genoa in 1563 and was made secretary of the Republic in the following year. Later he became a Jesuit (1565) and taught rhetoric in the Jesuit college at Rome. He is best known for his monumental *Historiarum Indicarum Libri XVI* (1588; best ed., Cologne, 1593), a valuable work, which occupied him for 12 years, and for which he gathered most of his material in Portugal. An edition of his Latin works was published at Bergamo in 1747.

MAFFEI, Scipione, Marchese (1675–1755). An Italian dramatist and scholar, born at Verona, June 1, 1675. He received his training with the Jesuits at Parma and then spent some time in the army under his brother Alessandro, a general in the Bavarian service, taking part in the battle of Höchstädt (1704). After his return to Italy he published the book *Della scienza cavalleresca* (Rome, 1710), in which he censured the practice of dueling. With two others he started in 1710 the *Giornale dei letterati*. Interested in the Italian stage of the Cinquecento, he prepared an edition of some of its best plays and prefixed thereto a dissertation of his own in the hope of improving the Italian drama, slavish in its imitation of Greek forms. But he did still more for the native theatre by composing his *Merope*, the first Italian tragedy of incontestable excellence, which was performed in 1713, printed at Venice, 1714, and frequently reprinted. Here he strives to attain the severity of the Greek, in contrast to the amorous insipidity of the contemporary treatment of this theme. In spite of numerous faults it has simplicity of style, and the emotions represented are frequently natural. It was translated into several foreign languages, and gave the type to which Italian tragedy of the eighteenth century conforms. Resembling the French tragedies in structure, it gave impetus to the tendency, already noticeable, which Maffei had striven to combat, to imitation of the French stage. It seems that Voltaire at first meant to translate it into French and only later decided to write an independent drama. The French writer did, however, imitate some scenes of the Italian work, and a bitter controversy arose between the two authors. Against an enemy of the stage, the cleric Concina, he directed the *Trattato de' teatri antichi e moderni,* which received the sanction of Pope Benedict XIV. Maffei's erudition revealed itself in a number of treatises, e.g., in the *Istoria diplomatica* (Mantua, 1727), the *Verona illustrata* (Verona, 1732), and the *Galliæ Antiquitates,* which he published at Paris (1733), after a journey of investigation made through Provence. While in France he studied the Jansenistic movement and dealt with it in his *Istoria teologica, etc.* (Trent, 1742). He attacked current prejudices in the *Dell' impiego del denaro* (1746), in which he demonstrated that loans on interest are not prohibited by moral law or by the Scriptures, and he renewed his attack in the *Arte magica* (1749–54). Works on physics, entomology, and other subjects show his scientific attainments. Consult: Maffei's *Opere* (21 vols., Venice, 1790) and the selected *Opusculi letterari* (ib., 1829, and Milan, 1844); Pindemonte, "Elogio del marchese Scipione Maffei," in the *Elogie di letterati italiani* (Florence, 1859); Giuliari, "Bibliografia maffeiana," in the *Propugnatore* for 1885, and A. Parducci, *La tragedia classica italiana del secolo XVIII anteriore all' Alfieri* (Rocca San Casciano, 1902).

MAFFIA. See Mafia.

MAF′FIT, John Newland (1819–86). An American naval officer, born at sea. He entered the United States navy as a midshipman in 1832 and was promoted to a lieutenancy in 1848. In May, 1861, he withdrew from the Federal service and entered that of the Confederacy. The next year he was placed in command of the *Oreto,* a steamer that had been built for the South at Liverpool. He carried the vessel to the island of Green Key, where he renamed her the *Florida* and took on board guns and ammunition that had been sent from Nassau. After a visit to Mobile he set out in January, 1863, on a long and adventurous cruise, in the course of which he captured a great many prizes, one of them alone being of the value of $1,500,000. Towards the end of the year, however, while his vessel was being repaired in the port of Brest, Maffit's health gave way, and he resigned his command. He died at Wilmington, N. C.

MAFFLEAN. See Paleolithic Period.

MAFIA, mä′fē-ȧ. A secret organization, especially prevalent in Sicily. Its origin is shrouded in mystery, but probably it arose gradually during the centuries of oppression under which Sicily and other parts of Italy suffered. The object of this society is to guarantee its members, who are known as Mafiosi, immunity for any crimes which they may commit. It is divided into sections, and there are passwords to enable members to recognize each other. There is a distinction between the Mafiosi of the mountains and those of the commercial cities. In the mountains the crimes are of the ruder sort, while along the coast and in the cities numerous assassinations and other terrible crimes have been perpetrated under the protection afforded by the Mafia. The essence of the constitution of the Mafia has been declared to be: ready, passive, and constant obedience to the head of the band; absolute silence as to the composition and enterprises of the band; material, moral, and pecuniary aid to all members, especially when arrested; never to have recourse to legal authority, but to refer all disputes to the leader of the band. The penalty for a violation of any of these obligations is invariably death. Members are subjected to an elaborate initiation, and the society claims in Sicily as members people from all ranks of society, and the whole of the island is still terrorized by the Mafia. General meetings are frequently held at the great cattle fairs, and the members of every grade assemble and adjust their reciprocal interests, devise their criminal projects, and plan their execution. The Italian government has frequently sought to suppress the Mafia, which in late years seems to be allied with anarchistic movements. In 1902 the government succeeded in convicting one of the leaders, Baron Palizzolo, a member of the National Legislature, for the murder of Marquis Notarbartolo, by transferring the trial to northern Italy. An account of this affair is to be found in *Die Zukunft* (Berlin, 1900). The baneful influence of the Mafia has also made itself felt several times in the United States, notably in New Orleans in 1890, where it was suspected of having caused the murder of the chief of police, and led to a riotous demonstration on the part of the citizens which resulted in the death of 11 Italians who were held in prisons under suspicion of complicity in the crime. A similar society is the Camorra (q.v.), which has attracted great attention. Consult: A. Vizzini, *La Mafia* (Rome, 1880); Giuseppe Alongi, *La Mafia* (Turin, 1886; 2d ed., Palermo, 1904); *Chambers's Journal,* vol. lxix (London, 1892); A. Cutrera, *La Mafia e i Mafiosi* (Palermo, 1900); E. C. Calou, *La Mafia* (Madrid, 1905).

MAGADAN. See Magdala.

MAGADHA, mŭg′hä-dȧ. One of the principal kingdoms of India when Alexander the Great invaded the country (327 B.C.). It comprised the larger part of Southern and Central India, and its power lasted till about 450 A.D. The capital of Magadha was Pataliputra, on the Ganges, which probably occupied the site of the present Patna. Seleukos, one of Alexander's generals, to whom Bactria was given, including the provinces on the Indus, attempted conquests beyond that river and was involved in war with the founder of the Maurya dynasty, Chandragupta, King of Magadha, called by the Greeks Sandrocottus (q.v.), who reigned from 315 to about 291 B.C. One of the Magadha kings, Bimbisara, is famous as the friend and patron of Buddha when he began his mission as a religious teacher. Consult M. C. Duff, *The Chronology of India* (London, 1899).

MAGADINO, mä′gȧ-dē′nō. A town in Switzerland on Lake Maggiore (q.v.).

MAGALHÃES, mȧ-gȧ-lyä′ĕNsh, Domingos José Gonçalves de (1811–82). A Brazilian writer, born in Rio de Janeiro, 1811, of an old Portuguese family. He was educated as a physician. In 1836 he was attached to the Brazilian Embassy at Paris. Returning to Rio in 1838, he became professor of philosophy in the Imperial College of Pedro II and then successively member of the Chamber of Deputies, chargé d'affaires at the courts of Turin and Naples, and Minister to Austria (1859), where he remained until 1867, when he became Ambassador at Washington (1867–71), whence he returned to spend several years at home. Finally he undertook the embassy at Rome and died there, July 10, 1882. Having begun as a classicist in his *Poesias* (Rio de Janeiro, 1832), he soon joined the Romantic movement, and between 1830 and 1840 he was one of the chief poets of Brazil. The first really important lyrics are, probably, his *Suspiros poeticos* (Paris, 1836). Mediocre works, and notable chiefly as the first tragedies by a Brazilian, are his *Antonio José* (Rio de Janeiro, 1839), *Olgiato* (ib., 1841), and *Amancia* (1844). The most famous work of Magalhães is the epos *A confederação dos Tamoyos* (Rio de Janeiro, 1857). The elegiac *Mysterios* is of 1857. Of his prose treatises there may be mentioned the *Ensaio sobre a historia litteraria do Brasil* (1836) and the *Factos do espirito humano* (1858). His *obras completas* were published at Paris in 1864 and later. Consult Wolf, *Ueber Dom J. G. de Magalhães* (Vienna, 1862), and id., in *La littérature brésilienne* (Berlin, 1863).

MAGALHÃES, FERNÃO DE (very commonly known by the Spanish form of his name, FERNANDO DE MAGALLANES, anglicized to MAGELLAN) (c.1480–1521). The discoverer of the Strait of Magellan, the first European navigator to sail across the Pacific Ocean, and the first person to circumnavigate the globe. According to certain documents his birthplace was Figueiro in Portuguese Estremadura, but there seems to be still greater evidence of his having been born at Villa de Sabroza, District of Villa Real, Traz os Montes, in Portugal. In any case, his father was Pedro de Magalhães, of a noble or hidalgo family, of the rank known as *nobles de cota y armas* (Portugal's fourth order of nobility). The date is not known. Having served as a page to Leonor, Queen Consort of João II (the Perfect), he entered service under their son, Manoel (the Fortunate), in 1495 and in 1504, as a volunteer, went to India with the first Viceroy, Dom Francisco d'Almeida, whence, after being twice wounded and rendering notable service, he was sent on various expeditions to Sofala, Malacca, Java, and the Spice Islands, in the years 1508–12, returning in this latter year to Portugal, with the grade of captain, that had been conferred upon him in 1510. In the treacherous uprising of the Malays in 1510 he fought bravely and ably, but it was not he who discovered the plot. Shortly after his return to Portugal he was raised to the rank of *fidalgo-escudeiro* (July 14, 1512); and the next year was stationed at Azamor in Morocco, capturing the city in August, being subsequently wounded and lamed for life, and conducting the operations against the Arabs, until he became involved in a dispute over the distribution of booty, which led him to go back to Portugal without the permission of his superiors. This is supposed to have influenced the King in refusing to grant him an increase in his royal allowance, for which he had petitioned, and this refusal in turn led him to forswear his native country and offer his services to the King of Spain in 1517. Magalhães had learned, probably from the captain of some stray trading vessel who had tried his fortunes in the southwestern Atlantic, that there was a water passage opening towards the west. Through influential friends at the Spanish court, chiefly Juan de Aranda and Diego Barbosa (who now became his father-in-law), he gained a hearing from Charles V, and his minister, Juan Rodríguez de Fonseca (the Bishop of Burgos), in which he presented his plans for finding a way westward to the Spice Islands. After many vexatious delays caused by the agents of the Portuguese government and by the Spanish officials who were jealous of the Portuguese mariner, Magalhães and Ruy Faleiro the astronomer signed an agreement with the King, March 22, 1518, by which they were appointed joint captains general and were to receive one twenty-fifth of the clear profits, and the government of any lands they might discover was vested in them and their heirs, with the title of *Adelantados*. Faleiro decided finally not to go, but Magalhães set sail from Seville with a fleet of five vessels, Aug. 10, 1519. In December he was at Rio de Janeiro, and in February, 1520, he reached the entrance to the Rio de la Plata. The next six months were occupied by difficulties with his crews and the loss of one vessel, so that it was Oct. 21, 1520, before he arrived at the entrance to the strait known by his name, but named by him Todos los Santos. A month later, November 28, he completed the passage and entered the Pacific Ocean. One of his vessels had meanwhile deserted him, and after many adventures made its way back to Seville, where it reported the destruction of the fleet. After a smooth and pleasant voyage (whence the name of Pacific given to this ocean), but during which they had suffered unspeakably from scurvy, due to scanty and bad provisions, Magalhães reached the Tiburones Islands in February, 1521, and on March 6 he was at the Ladrones. Ten days later he fetched Samar, and during the next six weeks visited the other islands of the Philippine group. Friendly relations were established with the ruler of the island of Cebú, with whom Magalhães joined his forces in an attack on the natives of the island of Mactán. While conducting a rear-guard defense after his partisans had been routed, Magalhães was killed, April 27, 1521. After this disaster one of the vessels was burnt, and the remaining two proceeded to Tidore, in the Moluccas, where the *Vittoria*, of which Sebastian del Cano had become commander, was refitted for the voyage back to Spain. She sailed Dec. 21, 1521, doubled the Cape of Good Hope on May 19, 1522, and on Monday, Sept. 9, 1522, dropped anchor in Seville Roads, having completed the first voyage around the world. Although Magalhães did not live to complete this particular voyage, he did circumnavigate the globe; for we must bear in mind that on his longest voyage eastward he had reached Banda Island at long. 130° E. of Greenwich, and that when he fell at Mactán Island he had sailed westward to long. 124° E. of Greenwich, thus by six degrees more than completing the circumnavigation. This feat has never been recognized at its full value, which would place it among the four leading achievements in discovery and exploration. Consult: *The First Voyage round the World by Magellan, Translated from the Accounts of Pigafetta, and Other Contemporary Writers . . .* by Lord Stanley of

Alderley for the Hakluyt Society (London, 1874); Diego de Barros Arana, *Vida e viagems de Fernão de Magalhães*, Portuguese translation of the Spanish Life by Fernando de Magalhães Villas Boas (Lisbon, 1881); F. A. Roberston (3 vols., Cleveland, 1906); F. A. Ober, *Ferdinand Magellan* (New York, 1907); G. M. Towle, *Magellan, First around the World* (Boston, 1914).

MAGALHÃES, FRAY GABRIEL DE (1609–77). A Jesuit missionary to China, born at Pedrogão in Portugal. He went to India in 1634 and to China in 1640, and was treated with great honor by the Emperor. Twice escaping martyrdom, he died peacefully and was honorably buried. He wrote *Nouvelle relation de la Chine*.

MAGALLANES, mä′gȧ-lyä′nås. A territory of Chile, comprising all that part of the country lying south of the forty-seventh parallel, which separates it from the Department of Chiloe (Map: Chile, E 7, 8). It includes the islands off the west and south coasts, and its entire area is estimated at 66,192 square miles. The mainland is a narrow strip of land largely mountainous and with extremely broken coasts, which fall into the sea in rocky and gloomy cliffs, in some places covered with glaciers. Numerous narrow channels enter far into the country, forming many peninsulas. The climate in that part of Chile is extremely damp and stormy, and rains occur during the greater part of the year. There are extensive pine forests, but very little agricultural land. Cattle, horses, and sheep are raised, and there are mines of coal, copper, and gold. Among the chief groups of islands belonging to the territory are the Wellington group, Madre de Dios, Hanover, Queen Adelaide Archipelago, and the western part of Tierra del Fuego. The population of the territory was 5170 in 1895, 17,330 in 1907, and in 1915 was estimated at 23,000, about half of whom live in the capital, Punta Arenas, on the Strait of Magellan.

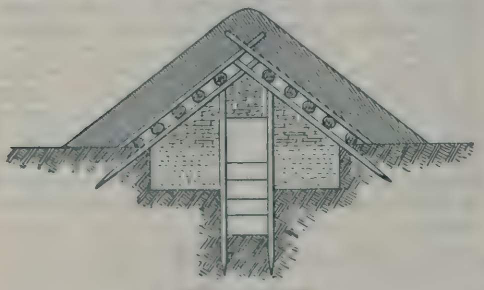
MAGAZINE, măg′ȧ-zēn′ (OF., Fr. *magazin*, It. *magazzino*, from Sp. *magacen*, from Ar. *makhāzin*, pl. of *makhzan*, storehouse, from *khazana*, to store up). The structure or cavity used for the storage of explosives. Where natural or artificial caves occur conveniently near mines or quarries, these are often used as magazines, but usually special buildings are constructed for such storage. All magazines should be cool, dry, clean, well ventilated, bullet proof, and fireproof. They should be constructed of such materials that when their contents are accidentally exploded the materials of which they are formed shall furnish neither burning brands to spread fire nor missiles to injure surrounding persons and property. The material found best suited is sand-cement mortar, consisting of coarse sand 6 parts and cement 1 part, as it offers marked resistance to penetration of rifle bullets and yet on explosion it is blown to a dust. The former characteristic is sought because magazines have frequently been made targets by foolish persons provided with firearms. The location of a magazine is of prime importance. It should be as convenient to the points of use and receipt of the explosives as possible, but sufficiently remote from highways, railways, inhabited buildings, mine buildings, and structures to inflict the minimum of damage in case of accidental explosion of the entire amount of explosive it is designed to carry. Natural or artificial mounds or barricades about a magazine serve to limit its danger. Some 30 years ago Colonel Majendie, H. M. Inspector of Explosives, studied the data of numerous accidental explosions and devised a table of distances that should separate buildings containing explosives from places frequented by man, and this was enacted into a regulation by the English Home Office and served as a model for other countries. Following the Lowell magazine disaster, Massachusetts enacted analogous legislation. More recently the manufacturers of explosives in the United States and the officials of the Bureau of Explosives of the American Railway Association have combined to investigate the data more fully, producing what is known as the American Table of Distances. To become law it must be enacted into legislation by the various States. The results are set forth below:

TABLE OF DISTANCES FOR THE ISOLATION OF MAGAZINES FROM INHABITED STRUCTURES

BARRICADED MAGAZINE		NONBARRICADED MAGAZINE					
Quantity of explosives stored	Proposed American distance	Proposed American distance	Massachusetts distance	Austrian distance	English distance	Italian distance	Prussian distance
Pounds	Feet	Feet	Feet	Feet	Feet	Feet	Feet
50	120	240	270	328	....	...	330
100	180	360	351	328	...	...	330
500	400	800	606	1,640	300	230	495
1,000	530	1,060	861	1,640	450	230	495
5,000	780	1,560	1,716	3,280	960	574	999
10,000	890	1,780	2,166	3,280	1,575	656	999
50,000	1,460	2,920	5,550	.....	5,550	1,640	...
100,000	1,835	3,670	10,500	.....	10,500	1,640	...
500,000	2,755	5,510	.....	.....	.....	.....	...
1,000,000	3,455	6,910	.....	.....	.....	.....	...

Hall, *Magazines and Thaw Houses for Explosives* (ib., 1912); C. Hall and others, *Investigations of Explosives Used in Coal Mines* (2d ed., ib., 1912); Hall and Howell, *Selection of Explosives Used in Engineering and Mining Operations* (ib., 1913); Munroe and Hall, *Primer on Explosives for Metal Miners and Quarrymen* (Washington, 1915).

Military. Modern military magazines are used as storehouses of powder and ammunition and not as formerly, when they were practically complete armories. General *storage* magazines well out of the range of fire are similar to the magazines used for the storage of explosives for powder factories and on large construction works. These are usually built of noninflammable material, as stone, brick, or concrete blocks of a thickness sufficient to resist penetration by a rifle projectile. They are placed behind hills or in hollows or on islands or otherwise with the idea of reducing to a minimum the damage that an accidental explosion may cause to life and property. In view of the objections to heating them artificially, special provision is made for ventilation to maintain even temperatures, keep down condensation, and to carry off fumes. *Reserve* magazines are near the zone of actual field operations. If not thoroughly protected from hostile fire by their location, ample overhead and horizontal cover should be provided artificially. Their dimensions are dependent on the number and size of guns served and the fighting period for which they are to be supplied. An *expense* magazine is one from which is issued the daily ammunition requirements of the troops to which it belongs. In fortifications—field or coast, permanent or temporary—the expense magazine is within easy access of the point of employment and is an important consideration in the general scheme of defense. Expense magazines are constructed according to the general designs of the fortifications of which they are a part and may be underground or built in the defenses and protected by bombproofs and similar devices. In fieldworks they are small rooms near the guns they serve and must be protected from hostile fire. This protection is normally afforded by building them partially in excavation at a lower level than the guns or by covering them, top, front, and sides, with earth or earth and masonry of thickness about one and a half times as great as the normal penetration of the projectiles to whose fire they will probably be exposed. The passageway to a magazine located in the field of fire should, if possible, contain an angle so that no fragments of a shell exploding outside shall reach the interior. The communications between the expense magazines and the guns should so far as practicable be out of sight of the enemy and protected from his fire, and reasonable protection given between expense and reserve magazines.



A FIELD MAGAZINE.

The design and construction of magazines for *permanent* land and sea-coast fortifications are governed by the general principles of fieldworks and permit of closer calculation as to location, cover, capacity, design, ammunition service, and ventilation. See COAST DEFENSE; FORTIFICATION.

Naval. An establishment used for the storage and handling of gunpowder and other explosives, and the preparation and storage of ammunition for large naval guns. Small-arm ammunition is stored, but not manufactured. Charges for guns are put up in bags ready for use and placed in water-tight tanks; fixed ammunition for smaller guns is loaded and boxed; and shells are loaded with their bursting charges and fitted with fuses and night tracers. The establishment consists of storage houses, filling houses, shell houses, laboratories, offices, etc., and has special facilities for the reception and shipment of ammunition and explosives by rail or water or both.

Ships. The magazines of a vessel of war are compartments designed solely for the storage of gunpowder or other explosives. Fixed ammunition is stowed separately, and projectiles are stowed in shell rooms. Magazines and other ammunition rooms are placed near the bottom of the ship, the tops of the compartments being well below the water line; for turret guns they are arranged about the base of the structure supporting the barbette tower and carrying the ammunition hoists to the turret. Magazines for other guns are placed where most convenient. Modern magazines are more complicated than those intended for the storage of black powder. In order to preserve its highest excellence, smokeless powder requires storage arrangements that will insure only a moderate range of temperature (75°–90° F.) and a nearly constant hygrometric condition. To secure these, magazines are double-walled and lined or lagged with sheet cork or some other nonconductor of heat. Refrigerating machinery maintains a constant temperature, and hydrating or dehydrating apparatus is used to maintain the required atmospheric state. When it is necessary to place magazines near internal sources of heat such as boilers, engines, coal bunkers, and the like, additional precautions are taken. All magazines are fitted with flooding apparatus whereby water may be rapidly admitted to avoid danger in case of fire. This apparatus is arranged for operation at some distance from the magazine. As powder is stored in water-tight tanks, it would not be injured if the magazine were filled with water. Fixed ammunition is usually ruined by submersion. Magazines and passageways leading to them are lighted by electric lamps reached from outside and separated from the interior by thick glass lenses. To prevent fire or bits of blazing material from entering magazines by way of the ammunition tubes or hoists, these terminate in handling rooms or passing rooms beside the magazines. Magazines for the storage of wet guncotton or safety explosives are located below water, usually near the torpedo rooms, but all dry guncotton for torpedo primers is kept above decks except during action or when anticipating it. Daily examinations are made of all magazines, and some are inspected more often. This is done to make certain of the temperature and hygrometric condition, but it also insures safety.

MAGAZINE GUN. See SMALL ARMS.

MAGAZINES. Periodicals devoted either to general literature, art, or science, or to some particular branch of human knowledge. The name magazine was first applied to them as being "storehouses" of varied information. For full account of their history, classes, and scope, see PERIODICAL.

MAGDALA, măg′dȧ-lȧ, or **MAKDALA**. The most strongly fortified town of Abyssinia, situated near the centre of the country, about 120 miles southeast of Gondar (Map: Egypt, D 5). It lies on the summit of an isolated basalt block, a mile square in extent, and with perpendicular sides in some places 2000 feet high. Magdala was stormed by the British forces under Sir Robert Napier on April 13, 1868 (see ABYSSINIA), and was destroyed. It was, however, soon restored to its former position, and is at present of considerable strategic value.

MAG′DALA (Lat., from Gk. Μαγδαλά), more properly **MAG′ADAN** (Gk. Μαγαδάν). The latter is the name in the Revised Version of Matt. xv. 39 given to the place to which Jesus and his disciples went after the feeding of the four thousand. The Authorized Version of this passage reads "Magdala"—a poorly supported variant—and the parallel passage in Mark has "Dalmanutha." Though the identification of the site is not certain, it is generally supposed to be on the western shore of the lake, some 7 miles south of the Plain of Gennesaret and some 3 miles north of Tiberias, near the group of huts which constitute the modern village of El Mejdel. At the upper border of the village is a watchtower, which has probably been reconstructed from an ancient tower, and suggests the derivation of the modern name (Heb. *migdāl* = tower). The puzzle of these three names in the Gospels is not easily resolved. They may refer to three distinct places in the same general district; or "Magadan" may have been turned by some copyist into "Magdala," as Herodotus (ii, 159) turns Megiddo into Magdalum; or El Mejdel being the traditional site of the home of Mary Magdalene, the better-known name, Magdala, may have obscured the less-known Magadan, and so forced its way into the text. In any case, Dalmanutha seems to be a separate place. See DALMANUTHA.

MAG′DALE′NA. The principal river of Colombia (Map: Colombia, C 2). It rises in the southwestern part of the country near the junction of the Central and Eastern Cordilleras of the Andes, and flows northward through the long and narrow valley formed by those two ranges until it enters the Caribbean Sea by two arms separating at the city of Barranquilla. Its total length is over 1000 miles. In its upper course it is an impetuous mountain torrent flowing through narrow, rocky defiles, forming numerous falls and rapids, and even in its lower course it has a very swift current. It is navigable for ocean steamers to the head of the delta at Barranquilla, and for steamers of 300 tons to Honda, 600 miles from its mouth. At Honda there is a series of rapids 20 miles in extent, above which the river again becomes navigable, though with difficulty, for 200 miles farther, to Neiva. Connection is made between the upper and lower courses by a short railroad passing around the rapids of Honda. Owing to the narrowness of its valley the tributaries of the Magdalena are all very short, with the exception of the Cauca (q.v.), whose length equals that of the main river from the point of junction. Until railroads are built the Magdalena will offer practically the only commercial route to the interior of Colombia, and it is now navigated by 40 regular steamers. The river was discovered in 1502 by Rodrigo de Bastidas. Consult H. J. Mozans, *Up the Orinoco and down the Magdalena* (New York, 1910).

MAGDALENA. The northernmost department of Colombia, South America (Map: Colombia, C 2). It is bounded by the Caribbean Sea on the north, Venezuela on the east, the Colombian Department of Santander on the south, and is separated from Bolívar on the west by the Magdalena River. Its area, including the peninsula of Goajira, is 20,463 square miles. The portion along the coast is occupied by the isolated range of Sierra Nevada de Santa Marta, exceeding in altitude 17,000 feet. The peninsula of Goajira is also more or less mountainous and along the eastern frontier is the Sierra de Perija. In the west and south the surface is mostly flat and occasionally swampy and overgrown in parts with dense forests. This part of the country is well watered and affords good grazing land. Bananas, coffee, sugar, cacao, cereals, and cabinet woods are the chief products, and grazing is carried on to some extent; hides and a fine breed of horses are exported. The mineral deposits, including gold, silver, copper, and coal, are believed to be important, but almost entirely neglected. Pop., 1912, 149,547, including about 40,000 uncivilized Indians, many of whom are still irreconcilably hostile to the whites. The capital is Santa Marta (q.v.).

MAGDALENA BAY. A bay and its port of Mexico, situated on the Pacific coast of Lower California (Map: Mexico, C 5). The bay is one of the best harbors on the Pacific coast, affording deep water in a lagoon or inlet 40 miles long and 12 miles wide, inside a sand bar or beach. The town is of slight importance and is the seat of a United States consular agent. It is a rendezvous for vessels of the United States navy detailed for target practice.

MAGDALENA BAY. A bay of northwestern Spitzbergen, discovered by Barents (1596), the scene of many polar activities. A whaling station of the Dutch in the seventeenth century, it was again occupied (1827) as headquarters of Russian sealers. It was the base of David Buchan's expedition (1818) and of the French scientific expedition (1838). Immediately north of it is Danes Island, whence Andrée made his fatal flight by balloon (1897), and where flourished the famous Smeerenberg (q.v.) four centuries ago.

MAGDALEN (mạd′lĭn) **COLLEGE.** One of the most beautiful and famous of Oxford colleges. It was founded as St. Magdalen Hall in 1448, and as the College of St. Mary Magdalen in 1458, by William Patten, better known as William of Waynflete. There were, in 1911–12, a president, 33 fellows, several senior demies, or half fellows (not exceeding 8), 51 junior demies and exhibitioners, 12 tutors, 4 lecturers, 4 chaplains, a choir, college officers, and 202 undergraduates. There is, in connection with the college, Magdalen College School, founded in 1480 as a grammar school preparing for the college and the university, after the manner of Winchester and Eton. Waynflete established also, with his new foundation, four professorships of moral and metaphysical philosophy, chemistry, physiology, and pure mathematics. The buildings, begun in 1475, are among the most beautiful in England. The grounds are extensive, comprising over 100 acres, including a deer park, and are most attractive. Magdalen has, from its foundation, been one of the richest of English colleges. It is rich in historical associations, and is especially to be remembered for the attempt of James II to force a Roman Catholic president on the college, one of the causes of his downfall. The college is still one of the strongest in Oxford. It presents to 40 benefices. Among the more distinguished of its members may be mentioned the grammarian Lily, Cardinal Wolsey, Bishop Foxe, Tyndale, John Lyly, John Hampden, Philpotts, Addison, Gibbon, and Lord Selborne. See OXFORD UNIVERSITY; WOLSEY; JAMES II. Consult: H. A. Wilson, *Magdalen College* (London, 1899), and E. Glasgow, *Sketches of Magdalen College* (ib., 1901).

MAGDALENE (mạd′lĭn) **COLLEGE.** A college at Cambridge University, England. Though nominally dating from 1519, it really began its career in 1542. It was founded by Thomas, Baron Audley, of Walden, and Chancellor of England, on the site of a Benedictine house founded in 1428, called Monks' Hostel, later Buckingham College. It was endowed partly by property in London and partly by spoils of the monasteries. One peculiarity of the foundation is that the master is nominated by the owner of Audley End, the country seat of the founder. The college possesses three libraries, the college library proper, the Peckard library, and the Pepysian library. The latter, contained in a separate building, is the collection of Samuel Pepys (q.v.), the diarist, and contains the manuscripts of his diary, together with other rare and curious documents, including the love letters of Henry VIII to Anne Boleyn, the whole having been given by Pepys, who was a member of the college. There were, in 1911–12, in Magdalene College, a master, a president, 7 fellows and 3 honorary fellows, college officers, lecturers, tutors, 12 scholars and exhibitioners, and 115 undergraduates. The college presents to six livings. Its distinguished members include archbishops Grindal, Usher, and Cranmer. See CAMBRIDGE UNIVERSITY; PEPYS. Consult E. K. Purnell, *Magdalene College* (London, 1904), and Tanner and Duff, *Descriptive Catalogue of the Library of Samuel Pepys* (2 vols., ib., 1914).

MAGDALEN HALL. Once a college at Oxford, England, established by William of Waynflete at the same time as his foundation of Magdalen College (q.v.). It was designed as a school for students previous to their admission to that college, and was presided over by one of the fellows of that foundation. In 1602 it became an independent hall and so remained till 1816, when Magdalen College resumed the premises, transferring the members of the hall to the premises of Hertford College, which were acquired for them in 1822. In 1874 the hall was dissolved and reincorporated as Hertford College. While it was still a hall, Tyndale, the poet Daniel, Lord Clarendon, Sir Henry Vane, and Hobbes were members. See OXFORD UNIVERSITY.

MAG′DALEN ISLANDS. A small group of islands belonging to Quebec and situated near the centre of the Gulf of St. Lawrence, 54 miles northwest of Cape Breton Island (Map: Nova Scotia, H 1). They consist chiefly of rocky knolls, often connected by sand bars, but contain some good soil suitable for agriculture. The inhabitants, who number about 5000, are chiefly supported by the productive cod, herring, and seal fisheries of the neighboring waters.

MAGDEBURG, mäG′de-bụrк; often *Anglicized*, măg′dē-bûrg. The capital of the Province of Saxony, Prussia, a first-class modern fortress, and one of the leading commercial cities of north Germany (Map: Germany, D 2). It is situated principally on the left bank of the Elbe, here divided into three arms, 88 miles by rail west-southwest of Berlin. The portion on the left bank of the Elbe comprises the Altstadt, with its surrounding suburbs of Wilhelmstadt on the west, Neustadt on the north, Sudenburg on the southwest, and Buckau on the southeast. The citadel and the Grosser Werder are on two islands of the Elbe, and Friedrichstadt is on the right bank. The abandoning of the fortifications to the north and south of the old town during the second half of the nineteenth century considerably increased the area of the city, and the additional space has been utilized for modern quarters, as well as for parks. The ancient and irregular plan of the old town has also been somewhat improved. The present fortifications of the city consist of the citadel, a remnant of the old fortifications, and a number of detached forts and redoubts, built in 1866, but since reconstructed and modernized. The old town is intersected from south to north by a wide avenue (Breite Weg), lined with many fine shops and old-fashioned gable houses. The Kaiserstrasse, west of this street, is the principal thoroughfare of the town; while along the banks of the Elbe are two fine esplanades known as the Fürstenwall and the Fürstenüfer. Noteworthy monuments are the one to the Emperor Otho the Great on the Alte Markt, erected by the municipality about 1290 and restored, and that to William I on the Kaiser Wilhelm Platz.

The cathedral of Sts. Maurice and Catharine, erected mainly in 1208–1363 and completed in 1521, is a magnificent Gothic structure, with some traces of the Romanesque. It has a fine polygonal choir, having carved stalls, many monuments and tombs, including those of Otho the Great and his wife Editha. The monument to Archbishop Ernest of Saxony, by Vischer, is especially elaborate, and there is a rare old chapter room. The cathedral contains many ancient objects of interest. The other noteworthy churches are the church of Our Lady, a cruciform Romanesque basilica of the eleventh century, attached to which are some beautiful cloisters, now used as a school; the Gothic church of St. Ulrich; the new church of St. Paul in Wilhelmstadt; and the synagogue. The most notable secular buildings are the Rathaus (1691), the old royal palace, now used as a museum, the administration building, the exchange, the railroad station, and the Reichsbank.

In the way of educational institutions Magdeburg has an agricultural college, a pedagogical seminary, three gymnasia, several Realschulen, an industrial art school, and a technical school. Among the collections are a public library of about 78,000 volumes, the archives of Prussian Saxony, and a museum with collections of paintings, engravings, sculptures, etc. The economic importance of the city is considerable. Besides being one of the principal centres of the beet-sugar industry in Germany, and well known for its fine fruit and vegetables, Magdeburg has great machine works. Among them are the famous Gruson Works at Buckau, now a part of the Krupp Works, and employing about 4000 persons. In addition there are extensive distilleries, chemical works, and manufactures of chicory, chocolate, tobacco, cigars, cement, artificial fertilizers, pottery, ribbons, gloves, and musical instruments.

The commerce is extensive, especially in beet sugar. Local manufactures, agricultural and colonial products, and books are also largely dealt in. Traffic is favored by frequent markets and an annual two weeks' fair in September. A considerable part of the commerce is carried on by water. At a cost of over $2,000,000, the city has latterly constructed a fine harbor, which accommodates the boats engaged in the Elbe transit trade, which amounts to some 4,000,000 tons of merchandise per annum. The municipal administration is in the hands of a chief burgomaster, a burgomaster, a council of 72 members, and a board of 25 magistrates. The municipality owns the water works and the gas works, both of which it operates at a profit. It also has a savings institution. The total figures as to population swelled very rapidly during the second half of the nineteenth century on account of the annexation of suburbs as well as of adjacent independent communities. From 84,401 in 1871 the figures rose to 202,234 in 1890, 229,663 in 1900, and 279,685 in 1910. The inhabitants are mostly Protestant.

History. Magdeburg first appears in history in the ninth century, and in 937 a monastery was erected there by Otho the Great. In 968 the city was made the seat of an archbishop, and was henceforth an outpost against the Slavs, becoming later an important commercial city and a member of the Hanseatic League. The municipal law securing administrative autonomy developed in Magdeburg in the Middle Ages, and known as the Magdeburg Right, was widely adopted in the granting of charters to cities in Germany and elsewhere. The city was very prominent during the course of the Reformation, which it adopted in 1524. It declined to make any compromise with Charles V, and hence was besieged in 1550 by Maurice of Saxony, whom in 1551 it was compelled to accept as overlord. It subsequently came under the control of Brandenburg, since the successors of its old archbishops, the so-called administrators, were chosen from the Hohenzollern. During the Thirty Years' War it suffered greatly; besieged unsuccessfully by Wallenstein in 1629, it was once more invested in 1631, this time by Tilly, the Imperial general. The citizens hoped for rescue from the Swedish King, Gustavus Adolphus, but he was delayed by negotiations with the Electors of Brandenburg and Saxony, who refused him passage through their territories. On May 20 (May 10, O.S.), 1631, the city was taken by surprise and destroyed almost completely. Thirty thousand of the inhabitants perished and not 200 houses remained standing. During the rest of the Thirty Years' War it changed hands repeatedly, until in 1638 Duke Augustus of Saxony became Administrator. By the Peace of Westphalia (1648) it was to become the possession of Brandenburg after the death of Duke Augustus. This occurred in 1680. From that time Magdeburg has shared the history of Brandenburg and Prussia. During the Napoleonic wars it fell into French hands (1806) and was given to the new Kingdom of Westphalia, but by the Peace of Paris (1814) was returned to Prussia. Consult, for its rôle in the Thirty Years' War, Klopp, *Tilly im dreissigjährigen Kriege* (2d ed., Paderborn, 1894–95); also Wolter, *Geschichte der Stadt Magdeburg* (3d ed., Magdeburg, 1901), and T. A. Dodge, *Gustavus Adolphus* (New York, 1906).

MAGDEBURG CENTURIES (Lat. *Centuriæ Magdeburgenses*). The name given to the first comprehensive Protestant work on the history of the Christian Church. The arrangement of this work was such that it devoted a volume to each century, whence the name "centuries," and the authors were called centuriators; it is called *Magdeburg* Centuries because begun in that city (in 1552). The chief of the centuriators was Matthias Flacius (q.v.), and his principal collaborators were Johann Wigand, Matthias Judex, Basilius Faber, Andreas Corvinus, and Thomas Holzhuter. The expenses of the work were borne by certain princes and noblemen. It was published at Basel (1559–74) in 13 volumes, bringing the history down to 1300. Six volumes of a new edition by Baumgarten and Semler appeared at Nuremberg (1757–65). Consult Schaumkell, *Beitrag zur Entstehungsgeschichte der magdeburger Zenturien* (Ludwigslust, 1898).

MAGDEBURG HEMISPHERES (so called from the place where they were invented). Two hollow hemispheres, of copper or brass, with their edges accurately fitting each other, one of which is furnished with a stopcock. When the edges are rubbed with grease, pressed tightly together, and the globe thus formed exhausted of air by means of an air pump, the hemispheres, which fell apart before exhaustion, are now pressed together with immense force; e.g., if they are one foot in diameter, they will, after exhaustion, be pressed together with a force of nearly a ton. This experiment was first performed by Otto von Guericke (q.v.) in 1654 at the Imperial Diet at Ratisbon.

MAGEE, m'gē̆′, WILLIAM CONNOR (1821–91). A prelate of the Church of England. He was born at Cork, Ireland; was educated at Trinity College, Dublin; and for a time was a curate in the latter city. Later he held two curacies in Bath, and became minister of Quebec Chapel, London, in 1859. The next year he returned to Ireland, where he became rector of Inniskillen, and dean of Cork in 1864, as well as dean of the Chapel Royal, Dublin, in 1866. He was appointed Bishop of Peterborough in 1868, and Archbishop of York in 1891, only a few weeks before he died. Dr. Magee was active in the organization of the Church Defense Society, which was intended to counteract the efforts of the Liberation Society to bring about the disestablishment and disendowment of the Church of England. He was president of the Church congress that met at Leicester in 1880, and from 1880 to 1882 was select preacher to the University of Oxford. He possessed great oratorical and controversial powers; contributed frequently to the *Fortnightly Review* and other periodicals; and published *The Gospel and the Age* (1884) and *The Atonement* (1887). A posthumous volume of addresses and speeches, and two sermons were published in 1891–92. Consult his *Life and Correspondence* by Macdonnell (London, 1896).

MAGELLAN, mȧ-jĕl′lan, FERDINAND. The discoverer of the Strait of Magellan. See MAGALHÃES, FERNÃO DE.

MAGELLAN, STRAIT OF. An irregular winding passage between the Atlantic and the Pacific oceans, separating the islands of Tierra del Fuego from the southern extremity of the South American continent, about lat. 53° south (Map: Chile, F 8). Its extreme length is 370 miles, and its breadth varies from 2½ to 70 miles. It has numerous bays and branches, especially at its southwest end, where it separates into channels inclosing a number of islands. The scenery along its shores is varied; at the east end the land is low and treeless, towards the middle it becomes mountainous and forested, in some places forming lofty precipices. Though the strait is generally free from shoals and other obstructions, its west portion is subject to impetuous currents and to rough and squally weather, rendering the passage unsafe for sailing vessels, which generally pass around Cape Horn. The strait is, however, very convenient for steamers. Its only considerable harbor is Punta Arenas (q.v.). The strait was discovered by Magellan in 1520.

MAGELLANIA, măj′ĕl-lā′nĭ-ȧ (Neo-Lat., from the proper name *Magellan*). A genus of Brachiopoda of the family Terebratulidæ. See TEREBRATULA.

MAGENDIE, mȧ′zhäɴ′dē̆′, FRANÇOIS (1783–1855). An eminent French physiologist and physician, born at Bordeaux. Through the influence of his father, who practiced as a physician in Paris, he became a pupil of Boyer, the celebrated anatomist. At the age of 20, after a competitive examination, he was appointed prosector in the faculty of medicine, and soon afterward a demonstrator. He was subsequently appointed physician to the Hôtel-Dieu. In 1819 he was elected a member of the Academy of Sciences, and in 1831 succeeded Récamier in the chair of anatomy in the Collège de France.

He was the first to prove experimentally that the veins are organs of absorption; he gave a more accurate account of the process of vomiting than had been previously given; he pointed out that an animal cannot live solely on any one kind of food; he investigated the physiological action and therapeutic uses of hydrocyanic acid and strychnine; he performed an important series of experiments on the cause of death when air is admitted into the larger veins; he made numerous experiments to determine the functions of various nerves and of different parts of the brain; and, lastly, he shares with Sir Charles Bell the honor of having discovered the separate functions of the two roots of the spinal nerves.

Magendie's chief physiological works are: *Précis élémentaire de physiologie* (Paris, 1816), which went through several editions and was enlarged into the *Eléments de physiologie,* which was translated into English and was for many years the best work on physiology in this language; *Leçons sur les phénomènes physiques de la vie* (ib., 1836–42); *Leçons sur le sang* (ib., 1839); *Leçons sur les fonctions et les maladies du système nerveux* (ib., 1839); *Recherches philosophiques et cliniques sur le liquide cephalo-rachidien ou cérébro-spinal* (ib., 1842). He was likewise the founder and for 10 years the editor of the *Journal de la Physiologie Expérimentale.*

MAGENTA, mȧ-jĕn′tȧ. A town in the Province of Milan, Italy, 16 miles west of Milan by rail (Map: Italy, B 2). It manufactures silk and matches. Its district yields excellent wine and an abundance of mulberries. It is chiefly famous as the scene of the victory by the French and Sardinians over the Austrians on June 4, 1859. The French and Italian troops were nominally commanded by Emperor Napoleon III and King Victor Emmanuel, but the victory was due to the tactics of General Macmahon (q.v.), who was created Duke of Magenta and marshal of France. Pop. (commune), 1901, 7974; 1911, 10,137.

MAGENTA. See COAL-TAR COLORS.

MAGERÖ, mä′gâ-rē. An island belonging to Norway, lying close to the coast of Finmarken, in the Arctic Ocean (Map: Norway, H 1). Its dimensions are 20 by 15 miles; it is very irregular in outline, deeply indented by fiords, and consists of a rocky plateau falling abruptly into the sea on all sides. It terminates on the north in North Cape (q.v.), the most northerly point of Europe, which rises almost perpendicularly from the sea to a height of 970 feet. Pop., 1910, 1732, mostly Norwegian and Lappish. A few shrubs and grass are found along the streams; lichens and reindeer moss abound, which support considerable herds of tame reindeer.

MAGGINI, mäd-jē′nē, or **MAGINI,** GIOVANNI PAOLO (1580–c.1630). An Italian violin maker, born in Brescia. He was a pupil of Gasparo da Salo, whose models he at first copied. Later he developed a model of his own, more accurate and elegant than those used by any previous makers, and also introduced a new way of cutting the wood used for the bellies of the instruments. It is supposed that he fell a victim to the plague which ravaged Brescia in 1628. Consult M. L. Huggins, *Giovanni Paolo Maggini* (London, 1892).

MAGGIORE, mȧ-jō′rȧ, LAKE. A body of fresh water, of which four-fifths is in the Italian provinces of Novara and Como, the northern fifth in the Swiss Canton of Ticino (Map: Italy, B 1). It is 636 feet above the sea, 37¼ miles long, 6 miles wide between Cerro and Feriolo, with an average width of a little over 2 miles and an area of 82 square miles. The greatest depth is 1221 feet. It is the longest lake in Italy, though surpassed in area by Lake Garda (q.v.). The river Ticino (q.v.) flows through the length of it from north to south, and the most important of the 20 other streams that feed it are the Maggia from the northwest and the Toce from the west. The north, west, and southwest shores rise into lofty mountains with snow-capped peaks, but the east bank gradually declines to the level of the plains of Lombardy on the southeast. The water in the north of the lake is green, in the south deep blue. The principal places on the lake are Locarno (q.v.), Magadino, and Brissago in Switzerland, and in Italy Cannobio, Maccagno, Luino (q.v.), Laveno, Intra, Pallanza, Baveno, Stresa, Arona (q.v.). As the St. Gotthard and St. Bernardino highways meet at Bellinzona, on the Ticino, 5 miles above the head of the lake, much of the Swiss and German trade with Italy formerly passed via the lake and the roads that parallel it. Steamboats every two or three hours in summer now connect the principal points on the lake (from Locarno to Arona in six hours), and the railroad between Bellinzona and Sesto-Calende, 36½ miles, skirting the east shore of the lake, is part of the system connecting Genoa (q.v.) with the north, via the St. Gotthard Tunnel. This road has turned some of the commerce from the port of Magadino. Along the west shore for 15½ miles runs the Simplon line from Pallanza, a famous winter resort, past Baveno, once the home of Queen Victoria, past Stresa, where the Italian nobility resort in summer, to Arona. Some manufacturing is maintained along the shore, especially at Cannobio, which markets wine, fruit, grain, cattle, hides, silk, and cotton goods. Laveno is at the mouth of the Boesio, on a bay that was once a fortified harbor for Austrian gunboats. The fortifications were pulled down in 1859, and a monument commemorates the Garibaldians who fell here in that year. A pottery now occupies the site of Fort San Michele; the other chief industry is silk spinning. Just behind Laveno rises the Sasso del Ferro (3485 feet), while a few miles to the northeast is Mount Nudo (4052 feet). Intra′ has important cotton, glass, and other factories, belonging mostly to Swiss proprietors. The famous Borromean Islands (q.v.) lie opposite Baveno.

MAG′GOT (probably from Welsh *maceiad*, *macai*, maggot, from *magu*, breed, Corn., Bret. *maga*, feed). The footless larva of any true fly. See Fly; Grub.

MAGI, mā′jī (Lat. *Magus*, Gk. Μάγος, *Magos*, from OPers. *maγu*, Av. *moγu*, magian, probably from Assyr. *maḥḥu*, magician, soothsayer). The name of the priestly order in ancient Media and Persia. Originally the designation Magi may have denoted members of a certain Median tribe, as we know from Herodotus (i, 101); but the religious association of the name seems to have existed from the earliest times. The name survives in the Magusæans, who settled in various places in Asia Minor. In Persian history the spiritual advisers of the Achæmenian kings are always called Magi, and their Median origin is generally acknowledged. Cyrus the Great was regularly attended by Magian priests; and, if we may believe Xenophon, it was Cyrus who first formally established them, although, as a priestly institution, the Magi must have been in existence before. A festival of the "slaying of the Magians" was long celebrated by the Persians in commemoration of the overthrow of the False Smerdis, a Magus, by Darius, and so of their not having been forced again to assume the Median yoke. The hatred of the sacerdotal caste evinced in this was probably more political and anti-Median than it was religious or anticlerical. The Median Magi were traditionally the priestly masters of the Persians; it was not lawful for a Persian to sacrifice without one of the Magi, and the power of this sacerdotal body must have been considerable in affairs of state as it was in religion.

There seems every reason to believe that Zoroaster was a Magian, if we may judge from references in Pahlavi literature, in the Greek and Roman writers, and in later Persian tradition. He was born in the very region of Media where the Magi abounded. (See Zoroaster.) In the *Avesta* (q.v.) the name Magus occurs certainly once in an allusion to a "hater of the Magi" (*Moγu-tbis*). The Parsis, or modern Zoroastrians, have kept up the tradition of the name, for the higher order of priests are called *Mobeds*, literally "Magian Masters." With regard to their doctrines it may be added that, so far as the Avesta may be presumed to represent the Magian code, and so far as we can judge from Herodotus, Plutarch, and other writers, the Magi recognized the principle of good and evil, light and darkness, as represented by Ormazd and Ahriman; they believed in a resurrection, a future life, and the advent of a savior; and in certain peculiar rites and customs, especially the preservation of the elements fire, earth, and water from defilement.

There seems little reason to question that the Magi exercised considerable influence even outside of Media and Persia, or that they were connected or associated with the priesthood of Babylonia and Chaldæa. Allusions in the Book of Daniel would imply this; and *Rab-mag*, in Jer. xxxiv. 3, may denote the "Chief of the Magi," although this interpretation is denied by some scholars. The Magian power was broken by the overthrow of the Persian Empire through Alexander's conquest and the consequent decadence of the Zoroastrian faith. Magism seems to have waned during the darker period of the Parthian sway, although it became paramount again under the Sassanian dynasty. To the condition of the priesthood during the darker period of the Parthians may be ascribed in some measure the evil sense associated with the word Magi by the Romans and by later Greek writers, although it was scornfully used as early as Sophocles—no doubt with an anti-Persian animus. The arts of divination, which the Magi must have practiced from the earliest times, seem to have brought the word into disrepute as wizard, necromancer, sorcerer, magician. Luke likewise uses it as a sorcerer (Acts xiii. 6). But the term is employed in its true sense by Matthew (ii. 1), of the wise men who came from the East to Jerusalem to worship Christ. The significance of this must be observed, because the Messianic doctrine was an old and established one in Zoroastrianism. Consult: Prášek, *Geschichte der Meder und Perser* (Gotha, 1906–09); F. V. M. Cumont, *Oriental Religions in Roman Paganism* (Chicago, 1911); id., *Les mystères de Mithra* (3d ed., Brussels, 1913); and especially J. H. Moulton, *Early Zoroastrianism* (London, 1913).

MAGI, Adoration of the. A popular subject with painters of the Renaissance and succeeding epochs. The scene is the well-known incident of the infancy of Christ in which the three wise men of the East, following the star of Bethlehem, worship and bear offerings to the infant Saviour. According to the mediæval tradition the Magis were kings, and they were constantly so represented in sacred art. They were usually attended by a great cavalcade of followers, clad in contemporary costume, which gave a fine opportunity to depict contemporary portraits and pageantry. Among the most celebrated versions by Italian painters are those by Gentile da Fabriano in the Florence Academy; Benozzo Gozzoli, in the Riccardi Palace, Florence, the most celebrated of all, and the best-preserved Renaissance fresco in the world; Filippo Lippi, in the Uffizi; Botticelli, in the Uffizi, with celebrated portraits of the Medici; Ghirlandaio, in the Uffizi and, best of all, in Santa Maria degli Innocenti; the remarkable version by Leonardo da Vinci in the Uffizi, unfinished but epoch-making in composition; Tintoretto in San Rocco, Venice, and elsewhere; and Veronese, who often depicted the subject (Brera, Milan, Dresden, National Gallery, London, Vienna Museum). Among northern painters it was portrayed by Quinten Matsys (Metropolitan Museum, New York), Albrecht Dürer (Uffizi, Florence), and often in the large canvases of Rubens, the finest examples being in the museums of Antwerp and Brussels.

MAGIC (Lat. *magice*, from Gk. *μαγική*, *magikē*, magic, sc. *τέχνη*, *technē*, art, from *μαγικός*, *magikos*, magic, from Μάγος, *Magos*, Magian, from OPers. *Maga*, Magian). The general term for the art or power of wonder working, with or without the assistance of supernatural agents.

Magic in Primitive Society. The facts of primitive magic are multiform and universal in their distribution. Many theories have been advanced to account for magical phenomena. Before reviewing some of these it will be well to give an account of the facts themselves. When the Ojibwa Indian desires to work evil on any one, he makes a small wooden image of his enemy and pierces its head or heart with a needle, in the belief that the object of his hate will be similarly affected; if the intent is to kill, the puppet is burnt with the accompaniment of magical words. In pursuit of a similar end the Malay takes bits of nails, hair, eyebrows, and other parts of the victim's body, and molds them into an effigy resembling the victim. For seven nights he scorches the figure slowly by holding it over a lamp while muttering incantations. Then the figure is burnt, and the enemy dies. To this day, in India, a magician will make an image of earth, taken from 64 filthy places, and will mix it with bits of hair, nails, etc. Then he writes the name of his enemy on the chest of the figure and maims it in some way in the assurance that the fate of the original will be that of its copy. Passing from evil to beneficent or harmless effects, we find that a barren woman in Sumatra, if she wants to become a mother, will make a wooden image of a child and hold it in her lap, believing that this objectification of her wish will lead to its fulfillment. The ancient Hindu mode of winning the love of a woman was to shoot an arrow into the heart of a clay image of the woman, the bowstring used for that purpose being of hemp, the arrow shaft of black *ala* wood, the feather an owl's plume, and the barb a thorn. In other numerous instances an entire group of people will perform the magical act. Thus, the magical ceremonies of the totemic groups of central Australia consist in elaborate dramatizations of the actions, cries, etc., of the totemic animal, and the supposed result of the ceremony is the multiplication of the animal. According to a widespread belief the behavior of wives in the absence of their husbands will affect the success of the latter in war or at the chase. Thus, among the Eskimo, when the men are away whaling, the women are supposed to spend their time in comparative idleness; if any garments are to be repaired, the women take them as far away from the sea as possible and do the work in small huts just large enough for one person; no work is done which is connected with any kind of noise, and in the huts of the men who are away no work whatever should be done. Among the Tshi-speaking peoples of West Africa, on the other hand, or among the Thompson Indians of British Columbia, or among the Californian Yuki, when the husbands are away on a war expedition, the wives will perform elaborate dances, in which the incidents of combat are dramatized, believing that such performances will insure the success of their distant mates. The belief is entertained by many peoples that barren or fruitful women may have an influence, for the better or worse, on vegetation. Thus, the African Baganda believe that a sterile woman prevents her husband's garden from bearing fruit; hence such women are often divorced. Among the Zulus, on the other hand, a pregnant woman is sometimes made to grind corn, which is then burnt among the half-grown crops to make them grow.

Similar ideas underlie practices connected with charms and amulets among many peoples and in many lands. Thus, among the Eskimo, men desirous of becoming great slayers of whales wear the foot of the guillemot, which is clever at catching cod. To give their boy the strength of a bear parents sew into the cap the skin from the roof of a bear's mouth. To acquire the fox's cunning a piece of the fox's head or of old dried fox dung is sewed into one's clothing. Among the Yuchi an amulet symbolizing a turtle will be worn by a child to induce sleep. The Indians of the plains represent on their shields spiders, lizards, and turtles, because they are hard to kill. The Arapaho warrior wears an amulet consisting of a bracelet of badger skin, with a gopher skin, an owl claw, some bells, feathers, seeds, and skin fringes. The badger skin stands for the horse's speed, the claw for the seizing of the enemy, the motion of the feathers drives away the enemy, and the bells warn the warrior of the impending fight. The Iroquois myths tell of a magic skin which is represented as covered by the hairs of all kinds of animals; when a hunter wants a plentiful supply of a certain animal, all he needs to do is to touch the appropriate hair while mentioning the number of animals desired, and the success of the chase is insured.

By such and similar devices crops are made to grow, women to bear children, enemies are maimed or killed, war parties made successful, the sun is saved from the clutches of an eclipse conceived as a monster, the rain is induced to fall in abundance, totems are multiplied, the qualities of animals are acquired by humans, the sick are cured, innumerable desires are satisfied, innumerable ends are attained or supposed to be attained. This is magic. But how explain the beliefs and practices underlying magical phenomena? To answer this question, various theories have been advanced by different authors, some of which must now be passed in review.

Theories of Magic. Interpretations of magic have been attempted by Tylor, Lang, Frazer, Marillier, Hubert and Mauss, Lehman, Marett, and Leuba. As space does not permit us to consider the views of all of these authors, we shall briefly discuss the theories of Frazer, Hubert and Mauss, Marett, and Leuba. Frazer distinguishes homœopathic, or imitative, and contagious magic. The first is based on similarity, the second on contact. The killing of an enemy by destroying his effigy is an act of imitative magic; the curing of a wound by anointing the weapon which caused the wound is contagious magic. Frazer distinguishes magic from religion. Religion, according to him, involves the belief in a superior deity exercising a moral influence on mankind. There is no such ethical element in magic, nor is there any belief in a god or spirit involved in magical procedure. Magic must rather be conceived as primitive science, which is based on the recognition of natural law, of an orderly succession of events. True, its postulates are erroneous, but centuries elapse before mankind becomes aware of fallacies underlying magic. When that moment arrives, the reign of magic wavers; religion, based on a belief in an all-powerful deity, takes its place; on the other hand, the theoretical postulates of magic prepare the way for the conceptions of modern science.

According to Hubert and Mauss the fundamental distinction between magic and religion lies in the fact that the latter is an organized cult; it is prescribed, official, while the former is secret or even prohibited; it may be permitted, but is never prescribed. True, the mechanism of magic involves three laws—that of similarity, contiguity, or contrast between the object forming part of the magical act and the object to be affected. But this does not suffice as an interpretation of magic; it is, above all, dynamic; it involves an active principle, a belief in power, *mana*, which pervades the universe, and the belief in which is traditional; it is not based on experience, nor is adverse experience able to upset it.

Marett believes that magic and religion were originally one, that the fundamental primitive fact is the belief in the supernatural, and that magic and religion did not become differentiated until a later period in the development of mentality. While magic is thus the positive handlings of the supernatural, it carries within itself the root of taboo (q.v.), the prohibited object or act, negative magic.

Leuba's treatment of magic is somewhat more analytical. As the fundamental postulates of magic, he distinguishes three principles: the principle of repetition, that which happened once will happen again; the principle of the transmission of an effect from one object to another, the relation involved being that of likeness, contact, or cause and effect; and the principle of the efficiency of will effort, which again appears in three forms—(*a*) cases where no belief in force is involved, as exemplified by superstitions connected with Friday, the number 13, the horseshoe, gambling luck; (*b*) cases in which the presence of *mana*, impersonal power, is the cardinal fact; (*c*) will magic proper, such as appears in spell, incantation, curse. As to the origin of magical beliefs, it is, according to Leuba, distinct from that of religion. Magical processes took their beginning in unteleological, spontaneous activities; these activities became magical only through accidental discoveries of their originally unpremeditated effects; then followed a more conscious elaboration of magical beliefs.

Among these theories of magic, and many others, Frazer's conception of magic as a primitive science must be singled out as most strikingly fallacious. Frazer's idea is based on what William James once called the "psychologist's fallacy." True, the processes of magic seem, from the standpoint of the outsider, to constitute a series of uniform successions of actions and effects, or believed effects. But is not the perspective of the participator in these magical processes a thoroughly different one? He surely does not believe in uniformities in nature, for, if such were his belief, the majority of magical practices would become unnecessary. He does, indeed, have an unbounded faith in the efficacy of the magical act or ceremony; but here, again, there is no concept of law, of uniformity, involved; it is the belief in power which is fundamental. Exercise the power, and the effect follows.

Nor is Frazer more fortunate in the distinction he draws between magic and religion. His definition of religion (q.v.) is obviously gratuitous. Of course, he is at liberty to use any definition of religion which to him seems appropriate, provided he remains consistent with his definition; on the other hand, by placing religion so high up in the scale of mental evolution, he is forced to make artificial distinctions which do not correspond to psychological reality. Had he permitted his definition of religion to be more elastic, he could not have escaped seeing that beliefs and ceremonies characterized by him as purely magical, such as the Australian *intichiuma*, involve emotional states which unmistakably belong to the category "religious." Nor can we side with him when he attempts to exclude the spirit from any participation in magical procedure, for acts which allow of but one psychological interpretation and must be regarded as magical are among one people purely mechanical devices, while among another spirits appear as the carriers or transmitters of magical power. Thus, the Australian medicine man seems to practice his craft successfully without the assistance of spiritual agencies, whereas the shaman of northwestern America or northeastern Siberia achieves the same results, but almost invariably in coöperation with a spirit assistant, a guardian spirit. Thus, we must take sides with the other authors here reviewed and against Frazer, in their contention that magic is not necessarily to be conceived as prior to or more primitive than religion.

Could the process of history be revealed, both magic and religion would doubtless be found rooted in beliefs held by man in most primitive times; nor does it seem justifiable to hold with Leuba that the origins of magic and religion were necessarily distinct. While in later periods the contrast between magical and religious procedure increases until, with the institutional side of religion, the differentiation between the two sets of phenomena becomes unmistakable and radical, the emotional nucleus from which both magic and religion proceed seems to be the same. The two fundamental concepts underlying both magic and religion are those of spirit and of power. Either one or the other, or both are always present in a magical or religious situation, in so far, at least, as it may be conceived as dynamic, i.e., as containing an active emotional thrill. For both magical practice and religious ceremony with their underlying beliefs tend to become conventionalized and deëmotionalized. The religion becomes a ritual and a dogma, mere formal shells of the dynamic experiences which had once given life and color to the magical or religious complex. While in that early condition magical and religious practices and beliefs largely overlap and fuse, the further progress of the two phenomena proceed along slowly divergent paths. Magic becomes more and more teleological and finally develops into a pure art or technique, while religion proceeds along the line of subjective elaboration which, beginning at a stage somewhat above the primitive, always reaches its goal in the elaborate emotional and conceptual world of the mature religious consciousness such as is revealed by the lives of the saints, prophets, and religious reformers.

Of the two ingredients of magic and religion, the conception of spirit is well known and understood; the conception of power, of magical potence, on the other hand, being a relatively recent product of ethnological analysis, requires some further words of explanation.

Conception of Impersonal Magical Power. The existence of a belief in primitive society other than that in spirit was first brought to our attention in connection with the Melanesian term *mana*. It does not mean spirit, but power, potency, life, mind—all concepts involving the idea of dynamic power, efficiency. Mana is not everywhere in nature, but it manifests itself through objects, beings, including man, spirits, gods. Wherever there is evidence of power, it is mana that is responsible for it, and the stranger, the more unusual, the power, the greater the charge of mana.

The evidence from Melanesia found support in America. J. N. B. Hewitt, an ethnologist of Indian extraction, interprets Iroquois religion as based on a fundamental concept, *orenda*, the meaning of which, as ascertained from the testimony of the Indians and by linguistic analysis, is very nearly that of the Melanesian mana. The late William Johns, another student of Indian blood, discusses a very similar concept among the Algonquin Indians, where it is known as *manitou.* It means power, mystery, and is impersonal, although it may ally itself with a being and thus become personal. The concept occurs most frequently in connection with the acquisition of the so-called guardian spirits, a custom not restricted to the Algonquin but found almost everywhere among Indian tribes. At the dawn of maturity the Indian youth withdraws to a shanty, built on an isolated spot in a forest. There he fasts, his scanty food being brought to him by some old man or woman, purifies himself until he is so clean "that the spirits can look through him." He dreams and finally sees a vision in which a spirit animal or being appears to him, a *manitou,* charged with magical power. The spirit confers various powers on the youth, such as the power of curing disease, or escaping the arrows of the enemy, or following game successfully. These powers are henceforth in the control of the youth, while the spirit remains his protector.

The discovery of this primitive concept of impersonal power filled a long-felt gap in the theories of savage religion. It was taken up with enthusiasm by the speculative wing of ethnologists. Marett proceeded to delight the anthropological world with his conception of *animatism,* a belief in impersonal power preceding animism; Pechuel Loesche applied the same concept in a novel interpretation of West African fetishism; Durkheim, finally, identified the concept of mana with the totemic principle, a still more primitive idea which he posited at the root of Australian totemism. And just as animism was so often conceived as a spiritual philosophy of nature, so the mana belief was conceived by some as a spiritless philosophy of nature, as a dynamism (Levy Bruhl, Leuba).

A dispassionate examination of these theories does not fail to reveal the tendency to make the mana belief a universal interpretative principle, a magic key to all the mysteries of primitive religion. Needless to say, no sufficient grounds can be adduced for regarding mana as a substitute for spirit, or as necessarily preceding spirit, nor as a primitive philosophy of nature. Moreover, the various beliefs which were so precipitately and so uncritically identified with mana may prove, on further examination, to differ in some aspects from mana or be altogether unlike it. However that may be, no doubt can be entertained as to the existence in the primitive mind of a concept of impersonal power, a magical substance which does things. Speculation as to the origin of such ultimate concepts is always difficult and dangerous. Thus, while our interpretative attempts must be taken for what they are worth, it may be noted that the coexistence of the mana belief with a belief in spirit possesses a high degree of psychological plausibility. Whatever the origin of the conception of a spirit, it must certainly have been developed under the stress of religious situations, the psychological rationale of which is a certain kind of emotional thrill. Now, while this emotional pressure served to further the conceptual elaboration of the idea of spirit, it seems also to have been directly objectified by the mind. In part this objectified thrill became absorbed by the spirit concept, for to exert power is of the essence of spirit; in part, however, it remained a free psychic element, impersonal, volatile, infectious, highly dynamic—a loosely objectified emotion, *that which causes the thrill.* Further we need not go. Within these limits the mana concept seems capable of doing capital service as one of the cardinal interpretative principles of primitive religion and magic.

Magic in Ancient and Mediæval Times. The magical lore and practice of the Chaldæans was extensive. About 200 tables containing the descriptions of Chaldæan magical processes, incantations, etc., are now preserved in the British Museum. They are copies of originals prepared by order of King Asurbanipal (884–860 B.C.), which were written in two languages, Assyrian and Accadian. From these tables we learn about the complicated demonology of the Chaldæans as well as the extensive use made by them of magical charms and amulets. Another important source is Sargon's work on divination, which contains 14 chapters devoted to prognostication by the flight of birds and the intestines of sacrificial animals, interpretation of various natural phenomena and of dreams, and to other topics. Sargon II (772–705 B.C.) had the work copied and systematized.

The Greeks added but little to magic that was original. They developed to a high degree the conception of the magic power of the spoken or written word. Medical activity among the Greeks was, up to the time of Hippocrates, in the hands of priests attached to the temple of Apollo and Æsculapius, who practiced divination (see NECROMANCY) and cured diseases by means of magical processes.

In Rome divination was practiced on an extensive scale. Divination by the cries and flight of birds was the favorite method. The cries of the crow, the raven, the night owl, and the rooster; the flight of the eagle and the hawk—figured in these magical rites.

The most complete data on Roman magic were probably contained in the famous books of Sibylla. According to tradition their number was originally nine, of which six were destroyed, while three were bought by Tarquinius Superbus. They were kept in the temple of Jupiter in the capitol, and a college of 15 men was permanently attached to them, who interpreted the meaning of their contents. The books were destroyed by a fire about 400 B.C.

After the advent of Christianity the belief in demons and magical powers did not disappear, but there arose a gulf between the power that was exercised by means of saints, angels, etc. (white magic), and that exercised by means of demons (black magic). Throughout the early Christian times the laity as well as the clergy believed in the influence of relics, of holy water; incurable diseases disappeared in the presence of the grave of Christ; etc. Beliefs of this sort lived on long after the period of their greatest diffusion, nor can modern civilization boast of complete emancipation from them. Witness the cures of Lourdes, the trade in relics in Palestine, the healing saints of Russia. The beliefs of early Christian times reacted viciously on the medical practices of the period, with the result that innumerable fantastic methods of curing disease were used and believed in, which almost completely replaced the much more scientific procedure instituted by Hippocrates.

Among the Scandinavian peoples we again find the supreme belief in the influence of word or thing. They distinguished four categories of magic devices—magic signs, magic sayings, magic drinks, and a most dreaded magical procedure called "Seid," which consisted of magic songs combined with some esoteric elements. No distinction existed among these peoples between black and white magic. The magic could be good or bad according to the results attained.

One of the widely diffused magical rites of the early Middle Ages was the ordeal (q.v.), which was a method of establishing guilt or innocence by means of a magical procedure. During that period the common people and the petty clergy preserved their belief in magic and demons, but the Church ruled otherwise; magic was no longer recognized by it, and witchcraft was regarded as impossible. Hence responsibility for an accusation in witchcraft fell upon the accuser. In 785 the Synod at Paderborn decreed that one who, misled by the devil, believes, with the pagans, that a woman can be a witch and burns her must be put to death.

In the course of the eleventh and twelfth centuries numerous individuals arose who refused to accept the teachings of the orthodox Church and preached various modifications of the accepted dogma. These were known as heretics. The current interpretation of heresy was that those who entertained it stood in communication with the devil, who induced them to forget the teachings of the Holy Church and poisoned their minds with discrepant opinion. They were persecuted and often put to death. In all such cases the accusation of witchcraft could not be officially proclaimed by the Church, which continued to deny the very existence of witchcraft. The change of attitude in these matters was marked by the writings of Thomas Aquinas (c.1226–74), who with great argumentative will attempted to demonstrate the reality of witchcraft. The first legal persecution of a witch took place in 1264, and from that time until some time in the eighteenth century untold thousands of innocent women were tortured and put to death in the name of the Church. The powers of witches, according to the belief of the time, were many and varied: they could induce hair, brushes, glass, needles, knives, nails, fishbones, worms, and scorpions, to enter the body of a person; by placing certain herbs on a knotted strap under the bed they could prevent childbirth, and then the number of knots would tell how many children were thus prevented from being born; they had the power of traversing space with incredible rapidity; and so on. The belief in witchcraft brought in its wake the utilization of various magical methods by means of which a witch could be recognized and her activity counteracted or forestalled.

Another stage in magical thinking is marked by the work of Agrippa (born at Cologne in 1456). In his book *De Occulta Philosophia* he propounded a theory of magic the substance of which consisted in an attempt to reduce magic to natural law. He taught that in the world of material and spiritual things the higher always influences the lower, and that the lower reacts; also that all things that belong to the same level influence each other. Thus, all magic was embraced in a universal natural law. Magic no longer depended on prohibited operations performed with the assistance of spirits, but in a teleological application of the natural forces such as were known to the physics, mathematics, and theology of the time.

Of the pseudoscientific offshoots of magic, two deserve a word of comment, astrology and alchemy. Astrology (q.v.) was the science of reading the stars and their movements, by means of which could be foretold earthquakes and political changes, the weather, the fate of infants, the outcome of diplomatic strife or war, the place where objects were hidden, etc. Alchemy (q.v.) was the art of transforming the metals into silver and gold. Many an alchemist of the time claimed to have found the goal of his strivings; but, whereas all such discoveries were doomed sooner or later to prove illusory, the persistent and systematic occupation with chemical compounds brought with it a gradual amassing of chemical knowledge and many a fruitful lesson in scientific experiment.

Modern Survivals of Magic. While the emotional thrill which once accompanied magical art is foreign to modern culture; while magic is no longer practiced either individually or publicly; while the phenomena once interpreted through magical concepts are no longer so interpreted, but have passed over to the domains of common sense or of science—modern culture has by no means freed itself from the survivals of magic, of beliefs in influences exerted through channels other than those given by the world of physical and psychic phenomena. Many people delude themselves with the belief of living in a thoroughly rationalized era until some one in the room opens an umbrella. The power of the evil eye has not lost all its terrors. People still "knock wood" to avert the consequences of excessive optimism. We have our lucky and unlucky days; the discovery that 13 guests have been invited to the dinner party prompts the hostess to make a hasty revision of her arrangements; an inconspicuous horseshoe continues to insure the well-being of many a household; many a college girl consults the color of the precious stone on her finger before committing herself to an important step; charms and amulets are carried by more men, women, and children among us than is generally believed, although some of those who carry them would be loath to admit the fact. Superstitions of this sort reap their richest harvests in circles of men and women whose success depends on a multitude of unforeseeable causes. The hunter, the fisher, are proverbially superstitious. Criminals, as a class, are superstitious. The gambler who ever finds himself at the mercy of a mysterious power knows a hundred signs and tricks by means of which to foretell, nay, even to control, the mood or intention of that power. The actor whose career is fed on handclapping is thoroughly versed in the lore of things and acts that are lucky and unlucky. The business man, to the extent to which business is a gamble, is, like the gambler, superstitious. While most of us do no longer see visions, we still dream dreams, and some of us thus know the future. How many there are who will scoff at the idea that a nun or a black cat may bring misfortune, but will take a side street to avoid a funeral procession. We laugh at the omens of classical antiquity, yet a trifling mishap at a marriage ceremony, or a birthday celebration or a presidential inaugural arouses adverse emotion to a degree quite disproportionate with the actual inconvenience or delay caused by the incident. One of the most deeply rooted and widespread survivals of magic belief is the faith in the influences exerted on the unborn child by certain experiences of the mother. It is probably an understatement to say that in our own society every second mother could tell of situations which she had sought in order favorably to influence the child she carried in her womb, through the channel of her own visual or auditory impressions, and of other situations which she had shunned in order to ward off from the child evil influences derived from similar sources. Thus does the past live in the present. See Legerdemain; Witchcraft.

MAGIC CIRCLE. See Circle, Magic.

MAGIC FLUTE. See Zauberflöte.

MAGICIAN OF THE NORTH. A name applied to Sir Walter Scott. It was also used by Johann Georg Hamann of himself.

MAGIC LANTERN. An optical instrument, by means of which magnified images of small transparent pictures can be thrown upon a white surface in a darkened room. It is a form of projection apparatus, and the name is usually given to the smaller instruments or toys, while stereopticon or projection lantern is applied to the larger and more practical instruments used for lectures and other demonstrations. See Projection Apparatus.

MAGIC MIRROR OF JAPAN. A few of the small, round mirrors used by the Japanese have the property of reflecting light to a screen or other surface so as to form images corresponding to the ornamental designs on their backs. As these mirrors do not differ in appearance from those that do not furnish such images, they have been termed magic mirrors, and their peculiar property furnished an interesting problem to scientists for a number of years. The Japanese hand mirrors in general are made of bronze, more or less convex on their reflecting side, with a polished surface of mercurial amalgam, and have on their back ornamented figures, such as flowers, dragons, and similar patterns. Professors Ayrton and Perry ascertained that there were certain portions of the reflecting surfaces corresponding to the designs on the back, which were more worn away in the course of polishing and thus became concave, or at least less convex than the rest of the surface. This circumstance, which results from a mere accident in the process of manufacture, served to explain the formation of the bright images on a dark ground when the mirror was used to reflect light to a surface. The magic mirrors, which are extremely valuable, have been produced in England by following this principle. Consult *Proceedings of the Royal Society of London*, vol. xxviii (London, 1879), and S. P. Thompson, *Light Visible and Invisible* (New York, 1910).

MÁGICO PRODIGIOSO, mȧ′ʜĭ-kȯ prȯ′dĭ-ʜĭ-ō′sȯ, El. One of the most striking plays of Calderón.

MAGIC SQUARE. A term applied to square arrays of numbers possessing the property that the sums of the various columns and rows, and of the two diagonals, are equal. In Fig. 1 this sum is 34. This square (the earliest known in Europe) was represented in Dürer's copperplate entitled *Melancholia.* The origin of magic squares is generally ascribed to China, and there is evidence in the *Yih King*, one of the earliest of the Chinese classics, that these squares were known there at a very early period. A magic square is found on one of the gates of the fortifications, in the Sanskrit characters, in the East Indian city of Gwaloir, but its antiquity is not such as to justify the assumption of Hindu origin. Magic squares were, however, certainly known to the Arab astrologers, who claimed for them a peculiar supernatural power and recommended them as talismans and amulets. A similar power is attributed to them to-day among the Hindus and to some extent in Europe. The natives of Tibet commonly wear them as amulets, and the Chinese make much use of them.

Fig. 1.

The magic square was a subject of much study by the Japanese mathematicians of the seventeenth century, and much ingenuity was shown in their treatment. Magic circles and magic wheels were also studied by them.

There are various methods for constructing magic squares of an odd number of cells. One of the oldest European methods of which we have any knowledge is described by De la Loubère in his work *Du royaume de Siam* (1691) and by him ascribed to the Hindus of Surat. The rule is as follows: Write 1 in the middle cell of the top row, 2 in the first cell to the right of the middle of the bottom row, then following the diagonal to the right until the right hand margin is reached; then go to the row above and take the left-hand cell, and again follow the diagonal upward to the right, and when the upper margin is reached, go to the lowest row and one cell to the right.

Fig. 2.

If progress is barred by a filled cell, go one cell down from the last number written and proceed as before. (See Fig. 2.) Another well-known method for an odd number of cells, due to Bachet de Méziriac (see BACHET), is as follows: Take, e.g., 25 cells. Arrange and number them as in Fig. 3. Then slide the outside cells to the sides opposite those on which they rest, thus filling all cells, as in Fig. 4.

FIG. 3.

It is not so simple to construct magic squares with even numbers of cells. The following method is, however, not particularly difficult.

FIG. 5.

Suppose the cells are filled, in the first place, with the numbers arranged in the natural order, as in Fig. 5.

It will be observed that the diagonals are already magic, since each equals the constant sum $\frac{n}{2}(n^2+1)$. It therefore only becomes necessary to arrange the rows and the columns to meet the definition. In the rows the sum of the numbers in the kth from the top is $\frac{n}{2}(n^2+1)-\frac{n^2}{2}(n-2k+1)$, and the sum in the kth from the bottom is $\frac{n}{2}(n^2+1)+\frac{n^2}{2}(n-2k+1)$. Furthermore, the number in each cell of the kth row from the top is less than the number in the corresponding cell in the kth from the bottom by $n(n-2k+1)$. Hence, if in these two rows we make $\frac{n}{2}$ interchanges of the numbers in corresponding cells, we increase the numbers in the kth row from the top, and decrease those in the kth from the bottom, by $\frac{n}{2}n(n-2k+1)$, and therefore make each of these rows magic. But in doing this it is, of course, necessary to leave the sum of the diagonals unchanged. It next becomes necessary to consider the columns. The procedure here is much the same as in the case of the rows. The sum of the numbers in the kth column from the left was originally equal to

$$\frac{n}{2}(n^2+1)-\frac{n}{2}(n-2k+1),$$

while in the kth column from the right it was

$$\frac{n}{2}(n^2+1)+\frac{n}{2}(n-2k+1).$$

The number in each cell of the kth column from the left was originally less than the corresponding number of the kth column from the right by $n-2k+1$. Hence $\frac{n}{2}$ interchanges are necessary as before, care being taken as to the diagonals. The difficulty comes in making the double interchange without disturbing the sums of the diagonals, but it can be shown that this interchange is always possible if $n > 2$. Starting with the initial square, the changes for a 4^2 square are shown as follows:

1	14	15	4
9	6	7	12
5	10	11	8
13	2	3	16

FIG. 6.

FIG. 7.

Interesting methods for constructing magic squares of an odd or an even number of cells are found in the works of Hoshino Sanenobu (1673), Isomura (1660), Seki Kowa (c.1665), Kurushima (c.1750), and other Japanese writers.

Besides magic squares, circles, magic wheels, magic polygons, and solids of various forms have been studied.

Horner, "On the Algebra of Magic Squares," in the *Quarterly Journal of Mathematics* (London, 1870); Günther, *Vermischte Untersuchungen zur Geschichte der mathematischen Wissenschaften* (Leipzig, 1876); Scheffler, *Die magischen Figuren* (ib., 1882); Lucas, *Récréations mathématiques* (2d ed., 4 vols., Paris, 1891–94); Ball, *Mathematical Recreations* (London, 1892); id., "Even Magic Squares," in the *Messenger of Mathematics* (ib., 1894); Schubert, *Mathematische Mussestunden* (3 vols., 2d ed., Leipzig, 1900); McClintock, "On the Most Perfect Form of Magic Squares," in the *American Journal of Mathematics* (Baltimore, 1897); Ahrens, *Mathematische Unterhaltungen und Spiele*, giving a very complete bibliography (Leipzig, 1901); W. S. Andrews, *Magic Squares and Cubes* (Chicago, 1908).

MAGIE, mȧ-gē′, WILLIAM FRANCIS (1858–). An American physicist, born at Elizabeth, N. J. He graduated in 1879 at Princeton University, to which, after study at the University of Berlin (Ph.D., 1885), he returned as professor of physics. In 1912 he became dean of the faculty. In 1909–10 Magie was president of the American Physical Society. His papers on the contact angle of liquids and solids and on the specific heats of solutions are noteworthy. His principal books are: a revision of Anthony and Brackett's *Physics* (1896); a translation of Christiansen's *Theoretical Physics* (1896); a translation of *The Second Law of Thermodynamics*, from memoirs by Carnot, Clausius, and Thomson (1899); *A Course of Lectures on Physics* (1904); *Principles of Physics* (1911).

MAGINI. See MAGGINI.

MAGINN, mȧ-gĭn′, WILLIAM (1793–1842). An Irish author, born in Cork. He graduated at Trinity College, Dublin, in 1811. From 1813 to 1823 he conducted a school at Cork and, beginning in 1819 with the doggerel-Latin version of *Chevy Chase*, for nine years contributed to *Blackwood's Magazine* a series of clever articles. In 1823 he went to London, where he was employed by Murray as European correspondent of the daily *Representative*. On his return to England he was for a time joint editor of the *Standard* and in 1830 assisted in establishing *Fraser's Magazine*. In this periodical first appeared his inimitable *Gallery of Literary Characters*, with excellent accompanying sketches by Maclise. In 1836 his attack on a novel by Grantley Berkeley occasioned an innocuous duel. The three essays on *The Learning of Shakespeare* (1837) and the *Homeric Ballads* (1838), versifications of portions of the *Odyssey*, display something of his real scholarship. His miscellanies exhibit the Anglo-Irish fancy in the full career of its wildest drolleries, and no "rattling Hibernian tale" outrattles the dare-devil exuberance of "Bob Burke's Duel with Ensign Brady" or that equally good "A Story without a Tail," reeking with convivial high spirits. Brought by intemperance and debt to the Fleet, where he dwelt even as Thackeray's "Captain Shandon"—he was the original of that character—he emerged thence, through the good offices of Sir Robert Peel, to die in extreme poverty. A collection of his writings was published in 1855–57 (New York, 5 vols., ed. by R. S. Mackenzie) and another in 1885 (London, 2 vols., ed. by R. W. Montagu). Consult H. S. Krans, *Irish Life in Irish Fiction* (New York, 1903).

MAGINNIS, CHARLES DONAGH (1867–). An American architect, especially of churches. He was born at Londonderry, Ireland, studied in London, and after 1886 practiced in Boston, Mass. (Maginnis and Walsh). He became a member of municipal and State art commissions and published *Pen Drawing* (1898).

MAGISTER, THOMAS. See THOMAS MAGISTER.

MAGIS′TER SA′CRI PALATII, pȧ-lā′shē-ī or pȧ-lä′tē-ē (Lat., master of the sacred palace). An officer of the papal court. It is said that St. Dominic while in Rome noticed that the servants of the cardinals were compelled to pass much time in idleness hanging around the doors of the Vatican while their masters were in audience. So he received permission to read the Scriptures to these people. When he went away another was appointed to succeed him in this labor. Out of this practice arose the present office, which is a very important one, as the incumbent is the censor of all books and pamphlets published by Catholics in Rome, a member of the congregations of the Index, the Inquisition and Rites, and is one of the important councilors of the Pope on theological matters. He is always a member of the Dominican Order.

MAGISTRAL DRUGS. See OFFICINAL PLANTS.

MAG′ISTRATE (OF., Fr. *magistrat*, from Lat. *magistratus*, magistrate, *magister*, master; connected with *magnus*, Gk. *μέγας*, *megas*, Skt. *mahant*, AS. *micel*, OHG. *mihhil*, great). In its broadest sense, a person clothed with power as a public officer. Blackstone employs it in this sense. Stating that the supreme magistracy was divided between King and Parliament, and discussing the powers of each, he proceeds to describe the subordinate magistrates of the most general use and authority, which, he tells us, "are principally sheriffs, coroners, justices of the peace, constables, surveyors of highways, and overseers of the poor." In this generic sense the term is used in the Declaration of Rights of Virginia, Massachusetts, and other States. One of these runs as follows: "That all power is vested in and consequently derived from the people; that magistrates are their trustees and servants, and at all times amenable to them." The writers of the *Federalist* gave this broad signification to the word when they designated the proposed President of the United States as the chief magistrate of the Union and compared his powers and duties with those of the governors or chief magistrates of the various Commonwealths.

At present the term is rarely employed in legal parlance in its generic sense, except in connection with the office of President or of Governor. In England it appears to be confined to ordinary justices of the peace (q.v.), who are appointed by the crown through the Lord Chancellor and serve without pay, and to the stipendiary or police magistrates, who are appointed by the crown on the nomination of the Home Secretary and receive salaries fixed by local boards, subject to the approval of one of the principal secretaries of state. The courts held by these officers, although technically described as petty sessions, special sessions, and quarter sessions, are popularly known as magistrates' courts. Stipendiary magistrates must be barristers of at least seven years' standing.

In the United States the meaning of magistrate, as a statutory term, has been frequently considered by the courts. While these decisions are not altogether harmonious, the prevailing view is that the term is to be understood in the narrow sense, now attaching to it in England, of "an inferior judicial officer, such as a justice of the peace." Police courts in cities are frequently known as magistrates' courts. Consult: Shirley, *An Elementary Treatise on Magisterial Law* (London, 1896); P. C. Dugan, *Law and Practice for Justices of the Peace and Police Justices* (5th ed., Albany, 1906); John Binns, *Binns's Justice, or Magistrates' Daily Companion* (Philadelphia, 1912); Edwin Baylies (ed.), *Bender's Justices' Manual of Civil and Criminal Law and Practice for Justices of the Peace and Police Justices in New York* (3d ed., New York, 1913).

MAGLIABECCHI, mä′lyȧ-bĕk′ē, ANTONIO DA MARCO (1633–1714). An Italian scholar and bibliographer, born at Florence. For 40 years he was a goldsmith. From his earliest years, however, he displayed an inordinate passion for the acquisition of book knowledge and, having mastered the Greek, Latin, and Hebrew languages, literally buried himself among books, disorderly piles of which encumbered every portion of his dwelling. In his daily habits he grew to disregard the requirements of social and sanitary life; and such was his avidity of study that he finally denied himself even the requisite intervals of repose. His memory was prodigious. Regarded as the literary prodigy of his times, he was appointed court librarian by Cosimo III, Grand Duke of Tuscany, and many tributes of respect were tendered him by royal and distinguished personages. He was intolerant of literary merit in others, was involved in several bitter literary squabbles, and died leaving, outside of his correspondence (ed. by Targioni, Florence, 1745), no written record of his encyclopædic knowledge. His library of 30,000 volumes he bequeathed to the Grand Duke, who gave it to the city of Florence, where it now forms part of the National Library. Consult Salvini, *Orazione funerale in lode di Antonio Magliabechi* (Florence, 1715). See FLORENCE, *Educational Institutions;* LIBRARIES.

MAGMA, măg′mȧ. In geology, the name applied to the bodies of molten mineral matter which by cooling produce the different kinds of igneous rocks. Such cooling takes place when the magma forces its way towards the surface, either by melting and breaking down the overlying structure or by egress through some fissure or vent, and comes into a region of lower temperature and pressure. In many cases the magmas apparently never reach the surface, but solidify at considerable depths under conditions which favor slow cooling and complete crystallization of the mineral materials. Rocks formed in this way are known as plutonic or deep-seated rocks and appear at the surface only long after their consolidation, when the original cover has been eroded away. Examples of the plutonic class are granite, syenite, and other coarse-grained types. If the magma pours out at the surface through an opening, it cools rapidly and forms a finely crystalline or even glassy rock, like rhyolite, basalt, and obsidian, which belong to the effusive or volcanic class. Besides their solid constituents, magmas always contain large amounts of water vapor and gases which exert a powerful solvent effect upon minerals; consequently they require less heat to maintain them in a state of fluidity than if acted upon by dry heat alone. The hot waters and vapors set free by the cooling of magmas doubtless have an important part in the formation of ore deposits. See IGNEOUS ROCKS; ORE DEPOSITS.

MAG′NA CHARTA, kär′tȧ, or GREAT CHARTER. The famous document granted by King John of England to the barons in 1215 and viewed by after ages as the basis of English liberties. The oppressions and exactions of a tyrannical sovereign called into existence a confederacy of the barons, or tenants in chief, of the crown, who took up arms for the redress of their grievances. Their demands were based on the charter voluntarily granted by Henry I at his accession in 1100, but added to this was a long list of demands for the removal of royal abuses or exactions which had come into existence since that time, or which had not been mentioned in that document. After several interchanges of messages a conference between the sovereign and the barons was held at Runnymede, near Windsor. King and barons encamped opposite each other; and after several days' debate John signed and sealed the charter with great solemnity on June 15, 1215. See ENGLAND; JOHN.

The Great Charter reared up a barrier against the abuse of the royal prerogative by a series of provisions for the protection of the rights and obligations of the feudal proprietor. It redressed a variety of grievances connected with feudal tenures, some of them now so long obsolete as to be with difficulty intelligible. There are minute provisions regarding the relief of heirs, wardship and marriage of heirs and heiresses, and marriage of the widows of tenants in chief. No scutage or aid is to be imposed without the authority of the common council of the Kingdom, except on the three great feudal occasions, of the King's captivity, the knighting of his eldest son, and the marriage of his eldest daughter. The liberties of the city of London and of other towns, boroughs, and ports are declared inviolable. Freedom of commerce is guaranteed to foreign merchants. Justice is no longer to be sold, denied, or delayed. The Court of Common Pleas, instead of, as formerly, following the King's person in all his progresses, is to be permanently fixed at Westminster; assizes are to be held in the several counties, and annual circuits are established. Regulations are made for the efficiency of the inferior courts of justice. The protection of life, liberty, and property from arbitrary spoliations is the most important feature of the charter. "No freeman shall be taken or imprisoned, or be disseised of his freehold, or liberties or free customs, or be otherwise damaged, nor will we pass upon him nor send upon him, but by lawful judgment of his peers, or by the law of the land"—a provision which recognized a popular tribunal as a check on the official judges, and may be looked on as the foundation of the writ of habeas corpus. No one is to be indicted on rumors or suspicion, but only on the evidence of witnesses. Protection is afforded against excessive amercements, illegal distresses, and various processes for debts and services due to the crown. The fines imposed are in all cases to be proportioned to the magnitude of the offense, and even the villein or rustic is not to be deprived of his necessary chattels. There are provisions regarding the forfeiture of lands for felony. Abuses connected with the royal forests were abolished by several provisions which were of so great importance as to lead to an incorrect statement by contemporary writers that a separate forest charter was granted. The independence of the Church is also provided for.

These are the most important features of that charter which occupies so conspicuous a place in history, and which establishes the supremacy of the law of England over the will of the monarch. From a distinctly constitutional point of view, however, the great importance of Magna Charta lay in its preserving the feudal idea of a contract between lord and vassals, between king and subjects, through the period of personal monarchy which was then already superseding the earlier Norman feudal monarchy, and thus making the development of the later parliamentary restrictions easy and natural.

The terms dictated by the barons to John included the surrender of London to their charge, and the Tower to the custody of the primate till August 15 following, or till the execution of the several articles of the Great Charter. Twenty-five barons, as conservators of the public liberties, were invested with extraordinary authority which empowered them to make war against the sovereign in case of his violation of the charter. Several solemn ratifications were required by the barons from Henry III and later rulers, and a copy of the Great Charter was sent to every cathedral and ordered to be read publicly twice a year. The copy preserved in Lincoln Cathedral is regarded as the most accurate and complete. The Great Charter and charter of the forests as issued in the reign of Henry III are printed with English translations, and prefixed to the edition of the statutes of the realm published by the Record Commission. McKechnie, *Magna Carta: A Commentary on the Great Charter of King John* (2d ed., New York, 1914).

MAG′NA GRÆ′CIA (Lat., Great Greece, a translation of Gk. Ἡ Μεγάλη Ἑλλάς, *Hē Megalē Hellas*). The name given in ancient times to that part of southern Italy which was thickly planted with Greek colonies. The origin of the name is uncertain, though it has been plausibly conjectured that it was given by the Achæan colonists in remembrance of their former home in the little district which originally was called *Hellas*. The language of Polybius, in whose writings the term first occurs, implies that it was believed to have been in use as early as the sixth century B.C. Some later writers include under the term the Greek cities in Sicily; others restrict it to those situated on the Gulf of Tarentum, but in general it is used to denote only all the Greek cities in the south of Italy. The oldest settlement is believed to have been Cumæ—though it is doubtful whether it and its colonies, Dicæarchia and Neapolis, were really embraced under the designation Magna Græcia—which must have been founded near the end of the eighth century B.C. The Greek colonization of southern Italy seems to have begun a little later than that of Sicily, but the dates commonly given must not be considered as more than approximate. The earliest settlement, not reckoning Cumæ, was said to be Sybaris (founded by the Achæans, 721 B.C.); next, Croton (by the Achæans, 710 B.C.); then Tarentum (probably by Laconian Dorians; the traditional date 707 B.C. is wholly uncertain); Locri Epizephyrii (by the Locrians about 685 B.C.; see Locris); Rhegium (by the Chalcidians; date of origin not known, but believed by some to be older even than that of Sybaris); Metapontum (by the Achæans, 700–680 B.C.); and Siris (by Ionians from Colophon, about 650 B.C.; it seems to have been seized later by the Achæan colonies near by). Later Thurii was founded in 443 B.C. by Greeks from many cities, under the leadership of Athens. These cities became, in their turn, the parents of many others. See the separate articles on the cities named above.

Of the earlier history of Magna Græcia we know almost nothing. It is noticeable that, while the Greek cities in Sicily were on the coast and so were essentially mercantile, the Italian Greeks pushed into the fertile plains of the interior, subdued the native tribes, and developed great agricultural communities, with a land-owning aristocracy. Not that trade was neglected, for with the great development of these cities during the seventh, and especially the sixth century, they carried on an active commerce with the Greeks of the east, the Etruscans of the north, and the native races of the interior, exporting grain and other natural products and importing the manufactures of Asia Minor and Hellas. The region was also the seat of an active intellectual life. Pythagoreanism developed in Croton and for a time exercised a powerful influence on the political life of that city. (See Pythagoras; Pythagoreanism.) The Orphic theology seems also to have found here a favorable soil for its growth (see Orpheus), and at Elea the philosophers Xenophanes and Parmenides founded the Eleatic school (q.v.). The cities never formed a permanent union, though from time to time we find several joined in temporary alliance. On the contrary, the wars between them were often bitter and bloody and contributed largely to the decline of the whole region. In the fourth century B.C. the tribes of the north, especially the Samnites, the Bruttii, and the Lucanians, began to press hard on the border cities; at the same time Dionysius of Syracuse endeavored to make his influence supreme. From this time the history is simply a record of endeavors of one or another city to keep back the rising tide of invasion, often by calling in the aid of foreign leaders. The most famous example is the alliance between the Tarentines and Pyrrhus of Epirus against Rome. The failure of this effort led to the capture of Tarentum by the Romans in 272 B.C. After that the Roman influence in the peninsula was supreme. The Second Punic War, when the presence of Hannibal induced most of the Greek cities again to seek their independence, completed the ruin of the region, and the cities rapidly sank into decay. Consult François Lenormant, *La Grande-Grèce* (3 vols., Paris, 1881–84).

MAG′NA MA′TER (Lat., great mother). A name under which the goddess Cybele (q.v.) was worshiped at Rome. A sacred black stone was solemnly brought from Pessinus in Phrygia in 204 B.C., and a temple was built for it on the Palatine Hill, where its remains still exist. The festival of the goddess, the *Megalesia*, fell in April.

MAGNAN, mä′nyän′, Bernard Pierre (1791–1865). A French marshal, born in Paris. He entered the army in 1809 as a volunteer and served under Napoleon in Spain and Belgium till the defeat at Waterloo. He was colonel in the army which invaded Spain in 1823 and went to Algeria in 1830. Censured for lack of energy in dealing with an insurrection in Lyons in 1831, he entered the service of Belgium as general of brigade, but in 1839 returned to France and was implicated in the first attempt of Louis Napoleon at Boulogne. (See Napoleon III.) In 1848 he tendered his services to Louis Philippe, but later sided with the Republicans and was energetic in bringing the Army of the Alps to Paris in June of that year to repress a formidable insurrection under the Republic, and another at Lyons in 1849. He allied himself with Louis Napoleon when the latter became President of France, and as head of the Army of Paris (1851) was his efficient instrument in the coup d'état of Dec. 2, 1851. Napoleon made him Senator (1852) and marshal (1853).

MAGNAN, Valentin (1835–). A French psychiatrist, born at Perpignan. He graduated in medicine at Paris in 1866 and the following year was made doctor at the Sainte Anne Asylum in that city. From the outset of his career he devoted himself to the study of mental disorders, and he wrote a number of technical works, especially upon alcoholism, one of which was crowned by the Academy of Medicine (1874). He became a member of the Academy in 1893. His publications include: *Etude expérimentale et clinique sur l'alcoolisme* (1871); *Des diverses formes de délire alcoolique et de leur traitement* (1873; Eng. trans., *Alcoholism*, 1876); *Recherches sur les centres nerveux* (1876; 2d series, 1893); *Leçons cliniques sur l'épilepsie* (1882); *Leçons cliniques sur les maladies mentales* (1887; later rev. eds.); *La paralysie générale* (1894), with P. Sérieux; *Les Dégénérés* (1895), with Legrain. His best works were collected and appeared as *Leçons classiques sur les maladies mentales* (2d ed., 1893). Some of his writings were translated into German by Paul Julius Möbius under the title *Psychiatrische Vorlesungen* (Leipzig, 1891). Magnan was an editor of the *Traité international de psychologie pathologique* (3 vols., 1909 et seq.).

MAGNARD, mȧ'nyär', Francis (1837–94). A French journalist, born in Brussels. He was on the staff of the *Gaulois* (1859), the *Grand Journal*, the *Causerie*, and other journals before joining that of the *Figaro* (1863), and his series of critical articles on current literature called *Paris au jour le jour* were published in both the *Evénement* and the *Figaro*. He was editor in chief of the latter periodical from 1876 and raised it to a high standard of excellence, from which it declined after his death. He wrote an anticlerical romance, *L'Abbé Jérôme* (1869), and *Vie et aventures d'un positiviste* (1876).

MAGNE, mȧ'ny', Pierre (1806–79). A French statesman, born at Périgueux, Dordogne. He studied law at Toulouse and became, in 1835, counselor to the Prefecture of Dordogne. In 1843 he was elected to the Chamber of Deputies and quickly gained a reputation as a financier. He was Undersecretary in the War Department in 1847 and in the Department of Finance in 1849. In the February revolution he was a member of the right centre. He became Minister of Public Works in 1851–52, Minister of Commerce and Agriculture in 1853, and Minister of Finance in 1855, keeping office till 1863, the last three years without portfolio. In 1867 he came into power again as Minister of Finance. He was replaced in 1869 by Ollivier (q.v.); returned to office with Broglie in 1873, and held the Treasury for a year. In 1876 he was elected Senator for Dordogne.

MAGNENTIUS, măg-nĕn'shĭ-ŭs, Flavius Popilius. A Roman Emperor of the West (350–353 A.D.). He was of barbarian extraction, but soon rose to the rank of count under the Emperor Constantine the Great. Entering the service of Constans, son of Constantine the Great, Emperor of the West, he was put in command of the troops that defended the Rhine. Presently he plotted the overthrow of Constans. With the aid of Marcellinus, count of the sacred largesses, his plot was successful. Marcellinus having invited the officers of the army, stationed near the city of Autun, to a banquet in honor of the birthday of his son, at a late hour introduced Magnentius arrayed in robes of royalty. The cry "Long live Augustus" was raised by several conspirators, Constans was assassinated, and Magnentius took possession of the palace at Autun (Jan. 18, 350). In a short time Gaul, Italy, and most of the western provinces acknowledged the usurper as Emperor. Constantius II (q.v.), the brother of Constans, and Emperor of the East, hastened to avenge the death of his brother and totally defeated Magnentius before the town of Mursa on the Drave, 351. Magnentius fled to Italy, thence to Gaul, where Constantius followed him, and again in 353 defeated him in the Cottian Alps. On the eve of being captured by his enemies, and deserted by the countries that had acknowledged him, he committed suicide at Lugdunum (Lyons), Aug. 11, 353. Constantius thus became master of the whole Empire. Consult *Cambridge Mediæval History*, vol. i (New York, 1911).

MAGNES, măg'nēz (Lat., from Gk. Μάγνης). An Athenian writer of comedies, who flourished in the earlier half of the fifth century B.C. He is the first comedian of whom we know that he won a dramatic prize; he introduced fantastic imitations of animals as part of the costume and the dances of the comic chorus. He was at first highly popular and won the first prize 11 times; but, according to Aristophanes (*Knights*, 520 ff.), he later lost his popularity.

MAGNE'SIA (Lat., from Gk. Μαγνησία). In ancient geography, the eastern district of Thessaly (Map: Greece, Ancient, C 2). It is a narrow and rocky strip of coast land, south of the Peneus and the Vale of Tempe and bordered on the west by Ossa and Pelion and by the Pagasæus Sinus. The Magnetes seem to have emigrated in part to Asia Minor, when the Thessalians occupied the region. Those who remained, while acknowledging Thessalian supremacy, were neither reduced to serfs (Penestæ) nor made members of the Thessalian confederacy, but were included among the allies. See Thessaly.

MAGNESIA. The name of two ancient Greek cities of Asia Minor. 1. The first was in the northern part of Lydia, near the Hermus, about 40 miles northeast of Smyrna, at the foot of Mount Sipylus, and was called Magnesia near Sipylus (Magnesia ad Sipylum), to distinguish it from the other (Map: Greece, Ancient, E 2). It seems to have been settled by Magnetes from Thessaly during the Æolian colonization, but, as was natural in a Greek city so far inland, it early fell under Lydian rule. It regained its prominence under the Seleucid kings of Syria and was the scene in 190 B.C. of a great battle in which the Romans defeated Antiochus III (Antiochus the Great). It was nearly destroyed by an earthquake in the reign of Tiberius, but was rebuilt and under the Byzantine emperors flourished greatly. After its capture by the Seljuks and later by the Ottomans, it retained its importance. Under its modern name, Manissa, it is a flourishing town with fine buildings, on the Smyrna-Alashehr Railroad. In this region, on or near Mount Sipylus, Greek legend located the Kingdom of Tantalus and the myth of Niobe. There are remains of very early settlements on the slopes of Mount Sipylus. 2. The second city of Magnesia was in Caria, in the valley of the Mæander, and was called Magnesia on the Mæander (Magnesia ad Mæandrum), to distinguish it from that near Mount Sipylus (Map: Greece, Ancient, E 3). It was about 15 miles from Ephesus and from Miletus. This city seems also to have been a colony of Magnetes, whose wanderings through Delphi and Crete to Asia were part of the legendary history of the city. It early became wealthy and powerful, but was destroyed in the first half of the seventh century B.C. by the Cimmerians (q.v.). Having been rebuilt, it was afterward conquered by the Persians. King Artaxerxes I assigned it to Themistocles as a residence; after Themistocles' death here, about 460 B.C., the inhabitants paid him honors as to a hero. In the neighborhood was a celebrated temple of Artemis Leucophryne. When about 400 B.C. the old site of the city was for some reason abandoned, the inhabitants withdrew to the higher ground around the temple, where a new city was built, which, though never very prominent, was later the seat of a bishopric. The temple was Ionic and of great beauty. Part of its sculptured frieze, representing the Amazons, was brought to the Louvre by Texier (q.v.), and the rest is in Constantinople. Excavations conducted for the Berlin Museum by Dr. Humann in 1891–93 laid bare the temple and also brought to light ruins of the Agora, theatre, gymnasium, and other buildings, as well as many inscriptions, including one containing the legendary account of the founding of the city. Under the Kings of Pergamos Magnesia still flourished. It helped Sulla against Mithridates. Under the Roman emperors it steadily declined. At present the city is most unhealthful. Consult: Kern, *Die Gründungsgeschichte von Magnesia am Maiandros* (Berlin, 1894); id., *Die Inschriften von Magnesia am Mæander* (ib., 1900); Carl Humann, *Magnesia am Mæander* (ib., 1904). For both cities, consult: the article "Magnesia," in Friedrich Lübker, *Reallexikon des klassischen Altertums*, vol. ii (8th ed., Leipzig, 1914); Baedeker, *Konstantinopel, Balkanstaaten, Kleinasien, Archipel, Cypern*, 346, 396 (2d ed., ib., 1914)—on page 396 is a plan of Magnesia ad Mæandrum.

MAG′NESITE (from *magnesium*). A magnesium carbonate that crystallizes in the hexagonal system and is isomorphous with calcite, dolomite, and siderite; it has a vitreous lustre and is either white, light yellow, or brown in color. Crystals of magnesite are rare, it being usually found in the form of irregular veins in serpentine and other magnesium rocks, being a deposition product either of the serpentine itself or of the original rock from which the serpentine is derived. It is found in many localities in Moravia, Styria, Silesia, and Norway; and in the United States in Maryland, New York, New Jersey, California, and Washington. This mineral finds considerable use in the preparation of magnesian compounds, such as Epsom salts, magnesia, and in the manufacture of paint, paper, and fire brick; also to some extent as an adulterant for the cheaper grades of soap. A variety containing iron is called *breunnerite*, or *brown spar*.

MAGNESIUM, măg-nē′zhĭ-ŭm *or* -shĭ-ŭm (Neo-Lat., from *magnesia*, from Gk. *μαγνησία* [sc. *λίθος*], *magnēsia* [sc. *lithos*], magnesian [sc. stone], magnet, from *Μαγνησία*, *Magnēsia*, a district in Thessaly, where magnetic stones abounded). A metallic element first isolated by Davy in 1808 and prepared in larger quantity by Bussy in 1830. Certain isolated salts of magnesium were known in the seventeenth century, the sulphate, e.g. (Epsom salt), having been found in the mineral waters at Epsom, England. The element is not found native, but its compounds are widely distributed as the minerals *magnesite* or magnesium carbonate, *dolomite* or magnesium-calcium carbonate, *kieserite* or monohydrated magnesium sulphate, *kainite* or magnesium sulphate with potassium chloride, *carnallite* or magnesium-potassium chloride, as well as numerous other minerals, containing smaller quantities. Magnesium also forms the chief constituent of many silicates, such as *augite, hornblende, olivine, serpentine, tourmaline*, and *meerschaum*. It is further found in the bones of animals and in the seeds of the cereals. The metal itself may be obtained by heating magnesium chloride with metallic potassium in a platinum crucible and washing out the resulting potassium chloride with water. It may similarly be made by the action of metallic sodium on magnesium chloride, but it is more cheaply obtained electrolytically. A mixture of carmallite (magnesium-potassium chloride) and common salt is fused and heated for a time with carbon; then ammonium chloride is added, and the fused mass is subjected to electrolysis, the positive electrode (when the chlorine is given off) being of carbon, while the iron cell containing the fused mass serves as the negative electrode and receives the metallic magnesium. To purify it, the metal is heated with molten carnallite.

Magnesium (symbol, Mg; atomic weight, 24.32) is a silver-white, lustrous, hard metal that is malleable and ductile, has a specific gravity of 1.75, and melts slightly below 800° C. (1472° F.). It is used in photography, signaling, and pyrotechny, as it burns readily when in the form of filings, wire, or ribbon, with a white light of great brilliancy; thus, a burning magnesium wire of 0.297 millimeter thickness produces a light equal to 74 stearin candles. Ordinarily the metal contains, in occlusion, considerable quantities of hydrogen gas and carbon monoxide, which are given off on heating. Magnesium combines with various other metals to form alloys, the most interesting of which are those with potassium and sodium, which decompose water at ordinary temperatures. A silver-white alloy of aluminium and magnesium, called *magnalium*, has been recommended for lens mountings, spectacles, etc. When ignited in the air or oxygen magnesium forms an *oxide*, MgO, which is a white, light, infusible, amorphous powder that is extensively used in the manufacture of crucibles, cupels, fire bricks, etc. It is also used, like lime, for the production of a light similar to the calcium light. (See DRUMMOND LIGHT.) The commercial article is obtained by prolonged ignition of the carbonate or the hydrate, both of which are derived from the saline deposits of Stassfurt, Germany. The oxide, as well as the carbonate, of magnesium finds use in medicine as a laxative and antacid. When mixed with water, the oxide gradually changes into the *hydrate*, which is also found native as the mineral *brucite*. The hydrate is used for extracting sugar from molasses, forming an insoluble, granular, crystalline magnesium saccharate, which, when decomposed by carbon dioxide, yields pure sugar. The *carbonate*, which is known commercially as *magnesia alba*, is prepared by precipitating either the sulphate or the chloride with sodium carbonate. The *sulphate*, which occurs as the purgative principle of various spring waters, is obtained commercially from the minerals kieserite and epsomite, or by decomposing dolomite with sulphuric acid. This salt (as Epsom salt) is largely used as a fertilizer, as a refrigerant cathartic in medicine, for dyeing with aniline colors, and for warp-sizing cotton. The *chloride*, which occurs native with potassium chloride as carnallite in the Stassfurt deposits, is used by cotton spinners as a thread lubricator and as a source for other magnesium salts. The *citrate*, which is official in the United States Pharmacopœia, is used in medicine as a laxative. Magnesium also forms an extensive series of metallo-organic compounds which are now widely used in synthetic organic chemistry. See GRIGNARD REACTION.

MAGNESIUM LIMESTONE. See DOLOMITE.

MAG′NET. A substance which has the power of attracting iron, nickel, cobalt, and certain other substances. A magnet may be either natural, as in the case of loadstone, or artificial, as in the case of magnets produced from iron or steel. See MAGNETISM.

MAGNETES. See both articles MAGNESIA.

MAGNET′IC CURE (from Lat. *magnes*, from Gk. *μάγνης*, magnet, from *Μαγνησία*, *Magnēsia*, a district in Thessaly, where magnetic stones abounded). It was held by physicians of old that the magnet exercised an important influence on the human body or on the bodies of certain persons; this being shown in the alleviation of headache, toothache, cramps, etc. It has, however, been proved that the magnet as such has no influence on animal organisms, and that accordingly all cures professedly resting on such action have been due to delusion or deceit. But it is quite otherwise with magneto-electricity and galvanism. Consult Peterson and Kenelly, "Magnetism," in *New York Medical Journal* (New York, 1892). See ELECTRICITY, MEDICAL USES OF.

MAGNETIC ELEMENTS. The quantities defining the earth's magnetic field, such as the magnetic declination, the magnetic inclination or dip, and the strength of the field. See COMPASS; DECLINATION; INCLINATION; TERRESTRIAL MAGNETISM.

MAGNETIC EQUATOR. A line supposed to be drawn on the earth's surface connecting the points at which a dipping needle assumes a horizontal position, i.e., where the magnetic *dip* (q.v.) is zero. It is a rather irregular curved line crossing the geographic equator in several places, but never receding from it more than about 16°. It is shown on the map of equal magnetic inclination in the article TERRESTRIAL MAGNETISM (q.v.). See also COMPASS; DEVIATION; ISOCLINIC.

MAGNETIC IRON ORE. See MAGNETITE.

MAGNETIC MERIDIAN. See COMPASS; DECLINATION; TERRESTRIAL MAGNETISM.

MAGNETIC MOUNTAIN. In the *Arabian Nights*, a mountain which attracted passing ships and by its magnetic power drew out the nails and fastenings and so destroyed the vessels. The tale appears in various works of literature.

MAGNETIC NEEDLE. See COMPASS; DEVIATION; MAGNETISM; TERRESTRIAL MAGNETISM.

MAGNETIC NORTH. See COMPASS; DECLINATION; TERRESTRIAL MAGNETISM.

MAGNETIC OBSERVATORY. An observatory whose chief purpose is to register, usually by photographic means, the variations, or fluctuations, of the earth's magnetism. See MAGNETOGRAPH; TERRESTRIAL MAGNETISM.

MAGNETIC POLES. See COMPASS; ISOCLINIC; TERRESTRIAL MAGNETISM.

MAGNETIC SEPARATORS. See ORE DRESSING.

MAGNETIC UNIT POLE. See MAGNETISM; ELECTRICITY, *Laws of Steady Electric Currents.*

MAG′NETISM. The name "magnet" is given any body which possesses the power of attracting pieces of iron. There are certain natural ores which have this power, but all magnets actually in use are artificial. The origin of the use of a magnetic compass as a means of obtaining approximately the direction of the geographical North Pole of the earth is unknown, but the first scientific work on the laws of magnets was done by William Gilbert (1540–1603), who published his researches and ideas in his great book *De Magnete.* Since his time the most important work has been done in connection with electric currents. (See ELECTRICITY.) Several attempts have been made to explain magnetism, i.e., to explain the magnetic action of a molecule of a magnetic substance by some electrical theory. Ampère advanced the idea that in each such molecule there is an electric current flowing in a fixed path. This idea is not, however, in accord with modern conceptions of the nature of a molecule. Weber tried to account for diamagnetism by the idea of induced electric currents in the molecules. A more modern theory is one in which molecular magnetism is regarded as due to rotation of electrons inside the atoms of magnetic substances. Weiss has recently shown that such atoms may be considered made up of a number of elementary magnets, called "magnetons"; thus, an atom of iron consists of a definite number of magnetons, an atom of nickel of a different number, etc. Langevin has extended this electronic theory and shown how it may explain all the main phenomena of magnetism.

In addition to attracting iron, magnets attract pieces of other kinds of matter, e.g., nickel, cobalt, manganese, chromium, and a few others, while they repel small pieces of bismuth, antimony, silver, and a few other substances. It was shown by Faraday that the question of repulsion or attraction depended entirely on the relative magnetic properties of the substance which is being acted on by the magnet and the material medium in which it is immersed—this last is, of course, generally air. Those bodies which when surrounded by air are attracted towards a magnet are called "magnetic" or "paramagnetic" substances; while those which under similar circumstances are repelled are called "diamagnetic." (See DIAMAGNETISM.) Faraday showed, too, that there is in neither case attraction or repulsion if the magnetic field is "uniform," i.e., if there is the same magnetic force felt at each point of the surrounding air.

There are two methods in general use for making artificial magnets: one is to take a bar or a needle of a magnetic substance, e.g., iron or steel, wrap an insulated wire around it like thread on a spool, and pass a strong electric current through the wire; the other is to take as before a bar or a needle of a magnetic substance and place it near a magnet. (A modification of the latter method will be described later.) The intensity of the magnetization is increased in both cases by hammering the bar while the magnetizing action is going on. It is found that a piece of steel magnetized in this way remains so for a long time, while a piece of iron loses its magnetization.

If a number of such bar magnets or magnetic needles are made, the following facts may be observed: If a magnet in the form of a bar or needle is suspended so as to be free to rotate around a vertical pivot, as in the mariners' compass (q.v.), it will turn and place itself in a generally north and south direction. The end of the magnet which points towards the north is called the "north pole" of the magnet; and the other, the "south pole." This proves that the earth itself has magnetic actions; and the plane which includes the centre of the earth and the direction of the magnetic needle at any point on the earth's surface is called the "magnetic meridian" at that point. It should not be thought that the "poles" of a bar magnet are definite points. Magnetic forces may be felt over the whole magnet, but of course more intensely near the ends. In any definite case the resultant of all these forces on any one outside body will pass through a certain point in the magnet, but this point will change with the position of the outside body.

If this magnet is floated on water, it is found that there is no translation, simply a rotation around a vertical axis. The magnetic field due to the earth must be uniform for any limited region on the earth; and this experiment proves that in a uniform field the forces acting on the two ends of a bar magnet are equal and opposite. This is sometimes expressed by saying that the north and south poles of a bar magnet have equal "strengths."

If a bar magnet is broken in two, both parts are magnets with poles at the ends. This leads to the idea that magnetism is a property of the molecules of the magnetic body. In fact, when a bar of iron is magnetized, its volume changes, its elasticity changes, etc.; if it is magnetized and demagnetized rapidly by using an alternating current in the magnetizing helix, its temperature rises. (If the temperature of a magnet is raised to red heat, it loses its magnetization.) Further, if a magnet is jarred or twisted, or if its temperature is raised, its magnetization is altered. In short, any physical action which affects the molecules of a magnet alters its magnetization; and any change in the magnetization alters the molecular properties. This establishes the fact that magnetism itself is a molecular property; and that if a molecule of a magnet could be obtained, it would have a north and a south pole like those of a bar magnet. It is impossible, therefore, to obtain a north pole apart from its equivalent south pole. There are no such forms of matter as magnetic conductors which enable the poles to be separated. This fact is illustrated by the phenomenon of induction described below.

If two bar magnets are brought near each other, it may be shown that like poles repel each other, and unlike poles attract each other; and further the action of a north pole of any one magnet on the north pole of another is equal and opposite to that of the south pole if the former is placed at the same distance from the north pole of the second magnet.

If a bar magnet is placed in air, and if a piece of any matter different from air is brought near it, this piece is observed to manifest magnetic forces at different points; it is said to be magnetized by "induction," and the forces of attraction or repulsion ordinarily observed with magnets acting on iron, etc., are due to the presence of these "induced charges" of magnetism. If the piece of matter is of iron or any magnetic material, it is magnetized in such a manner that, if it is nearest the north pole of the magnet, its face which is next this pole is a south pole. (If the piece of matter is bismuth, the opposite is true.) It is perfectly easy to explain the induction of iron or other magnetic substances if it is assumed that each molecule of the magnetic substance is a magnet. Then, before this body is put near the magnet, the molecular magnets are standing at random, and there is no external action; but when it is brought near the magnet, each molecular magnet is acted upon by a couple which tends to make it turn and point towards the magnet, its south end being attracted towards the magnet's north pole. By this action all the little magnets are more or less arranged in order; and at the end near the north pole of the magnet there will be almost nothing but south poles of the molecules, etc. All the facts of magnetization of iron, e.g., saturation, hysteresis (q.v.), etc., can be explained by this idea of the molecules of iron, nickel, etc., being themselves magnets.

If a bar of iron is placed lengthwise between two magnets, connecting two opposite poles, and if two bar magnets with their opposite poles together are held nearly vertically at the middle point of the iron bar and then drawn slowly apart along the iron bar, it becomes magnetized, especially if the process is repeated several times. This is known as the method of "divided touch." Its explanation is evident from the theory of molecular magnets.

It is observed that, if a small magnet is pivoted, free to turn, inside a helix of wire, it will place itself parallel to the axis of the helix when an electric current is passed through the latter. It is evident, then, why a bar of iron placed through the helix becomes magnetized by the action of an electric current.

The law of action of magnets on each other may be given if the words "equal poles" and a unit magnetic charge or "unit pole" are defined. Two magnetic poles are defined as being equal if they have the same action on any third pole; and a unit pole is chosen to be such that when acting on another unit pole at a distance of 1 centimeter in a vacuum the force is 1 dyne. To find the numerical value to give any pole it is necessary to find what combination of unit poles has the same action on a third pole. Experiments then show that the action of a pole whose magnetic charge is m upon one whose charge is m' at a distance r centimeters apart varies directly as the product mm' and inversely as r^2 and is different for different surrounding media. This law may be expressed $f=\frac{mm'}{\mu r^2}$, where μ is a quantity which differs for different material media. It is called the "magnetic permeability" or the magnetic "inductivity." (Cf. the quantity K in *Electrostatics* under ELECTRICITY.)

The dimensions of a magnetic charge may be at once found. The square of a charge has the dimensions of $\mu r^2 f$, i.e., μL^2MLT^{-2}. Hence the charge itself has the dimensions $L^{\frac{3}{2}}M^{\frac{1}{2}}T^{-1}\mu^{\frac{1}{2}}$.

This law of magnetic action has been verified approximately by Coulomb, it being called his law, so far as the statement that the force varies as $\frac{mm'}{r^2}$ is concerned, and later by Gauss, who used an indirect method, and by the countless experiments and calculations made daily by electrical engineers. The importance of recognizing the effect of the surrounding medium was first emphasized by Faraday.

The region around a magnet is called its "field of force"; the "intensity" of the field at any point is the force which would act on a unit north pole if placed there; the "direction" of the field is the direction of the intensity; a "line of magnetic force" is a line drawn in a magnetic field so as to indicate by its direction at any point that of the field at that point; a "uniform field" is one in which the lines of force are all parallel, and the intensity is the same at all points. Such a field is a limited region on the earth due to magnetic action of the earth, or the space between the poles of a horseshoe magnet or between the field magnets of a dynamo. The intensity of any uniform field may be measured by several means; the best for many reasons is that of Gauss. If a magnet of any kind or shape is suspended in a uniform magnetic field, free to turn around an axis perpendicular to the direction of the field, it will turn and take some definite position; in order to keep this magnet in a position at 90° from this against the action of the field of force will require the application by some external agency of a certain couple or moment; the amount of this couple, if the intensity of the uniform field is unity, is called the "magnetic moment" of the magnet about the given axis. If the magnet is uniformly magnetized—i.e., if in case it is broken into two, three, etc., equal parts, they will all be alike in every way—the magnetic moment divided by the volume of the magnet is called its "intensity of magnetization." If the magnet is a bar or rod or wire, uniformly magnetized, so that there is no magnetization except at the ends, it is called a "solenoid," and the distribution of magnetic charges is called "solenoidal" (thus, the magnetic action of a long helix of wire carrying an electric current is approximately solenoidal). If the magnet consists of a thin sheet with all the molecular magnets side by side, having their north poles on one face of the sheet and their south poles on the other, it is called a "lamellar" distribution. (Thus, the magnetic action of a single loop of wire carrying an electric current has this lamellar property.)

Lines of magnetic force may be drawn by placing a small magnetic needle at different points in the field of force and noting its direction. Still another method is to sprinkle iron filings through the field, e.g., over a glass plate or smooth piece of paper; each filing becomes magnetized by induction, and if the filings are jarred slightly each will turn and place itself along the line of force at the point where it is. (Actually there will be a force of attraction towards the magnet; but it is resisted by the friction between the filing and its supporting plate or paper.) It may be observed immediately that lines of force join opposite poles of magnets in the air; and, since the molecules of a magnetic substance are also magnets, the lines of force can be imagined as proceeding from molecule to molecule inside the magnet. In this sense lines of magnetic force are continuous closed curves—not like lines of electric force which end on charged surfaces. Tubes can be imagined constructed, by choosing somewhere in a magnetic field a small closed curve and drawing through each point of it the line of force. Such tubes are continuous and closed like an ordinary piece of rubber tubing with its two ends brought together. If the cross section of these tubes is so chosen that the number passing out at the north pole of a magnet on which there is a magnetic charge m is $4\pi m$, they are called "tubes of induction." It is shown in electricity that if the number of such tubes passing through a closed circuit of wire is changed, there will be an induced current in the metallic circuit; the total quantity of electricity carried by this current varies directly as the change in the number of tubes of induction. This gives the simplest and most accurate method of determining the distribution of magnetic charge over the surface of a magnet. If the magnet is in the form of a rod, a coil of wire having its two ends joined to a galvanometer may be slipped over it. The tubes of induction enter the magnet wherever there is any south magnetic charge, i.e., where the south poles of the molecular magnets reach the surface, and leave it where there is any north magnetic charge, i.e., where the north poles of the molecular magnets reach the surface. Tubes are crowded together about the middle of the rod and then escape at the sides and north ends, returning into the sides and the other pole of the rod. As the small exploring coil is pushed along the rod from the centre to the north end, the number of tubes inside decreases, owing to the passage out from the rod of the tubes of induction; the induced quantity of electricity measures the decrease in the tubes, i.e., the number of tubes leaving the sides of the magnet, and therefore the magnetic charge over them, because a unit charge corresponds to 4π tubes.

The energy of a magnetic field is identical with that associated with an electric current. (See ELECTRICITY.) Whenever attraction or repulsion is observed to take place, the motions must be such as to decrease the potential energy and increase the kinetic, at least temporarily.

Magnetic Properties of Iron. We have seen that when an electric current is sent through a coil or spiral of wire the coil is found to have the properties of a magnet; that is to say, it will attract bits of iron, deflect a magnetic needle, etc. The region around the spiral when the current is flowing in it is called a magnetic field. The intensity or strength of the field is defined as the force which would act on a unit north pole, and so varies from point to point in the neighborhood of the spiral. In describing this field the convention has been adopted of imagining the field traversed by lines of force which indicate by their direction the path the unit north pole would follow if free to move. When the field has unit strength, it is said to contain one line of force per square centimeter perpendicular to the

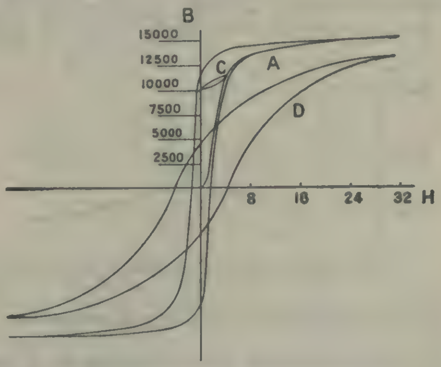

FIG. 1. CURVES OF MAGNETIZATION.

direction of the line. It may be shown that the intensity of the field, or the number of lines of force per square centimeter within the spiral carrying the current, is represented by the formula $H = 0.4\pi ni$, H being the intensity of the field, n the number of turns per unit length of the spiral, and i the current strength in amperes.

If now the coil is wound on a core of iron, nickel, or cobalt, its properties as a magnet are found to be greatly intensified; that is to say, the number of lines of force per square centimeter is increased, i.e., the core has become magnetized. The number of lines of force per square centimeter within the core is called the *induction* and is usually designated by the letter B. The ratio of the induction B to the intensity of the field H is called the *permeability*, μ; i.e., $B = \mu H$. For air B is evidently equal to H, since we have defined H as the number of lines of force per square centimeter when the coil has no core. Thus, μ for air is equal to 1.

The permeability μ differs widely in different materials and in any one material may vary widely with the induction B. For in any one of the metals above mentioned with a uniformly increasing H, B increases at first slowly, then rapidly, then slowly again, entering a region in which the increments of B are exactly equal to the increments of H. In this region the material is said to be saturated. This process is shown in the curve A in Fig. 1. It will thus be noticed that with increasing values of H the ratio of B to H varies widely. In Fig. 2, a curve is given which shows the variation of the permeability in a given specimen of iron for different values of H; as indicated, μ increases rapidly at first, corresponding to the rapid increase in B, then decreases, corresponding to the portion of the BH curve in which the material is approaching saturation. The values of the permeability and so of the induction which may be attained in iron are greatly in excess of those obtainable in other materials, and this together with the fact that it is so much more common in nature has led to its widespread adoption in the construction of electric machinery and all apparatus in which it is necessary to have strong magnetic fields.

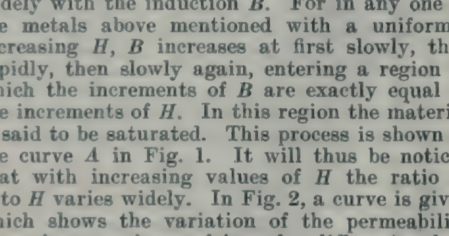

FIG. 2. CURVE SHOWING VARIATION IN PERMEABILITY.

The behavior of iron when subjected to a magnetizing force is usually represented by the curve between the induction B and the intensity of the force H mentioned above. Such a curve taken from a particular sample of soft iron is shown in curve A in Fig. 1. With iron in the neutral state, i.e., starting from $H = 0$, with increasing H, B increases slowly at first, then very rapidly, then more and more slowly, the curve approaching a slightly inclined straight line a little above 15,000. This is the region commonly spoken of as the saturated state; i.e., although H may be continually increased, the corresponding increase in B does not exceed that of H. If now H be decreased, the values of B will not traverse the same path that they did for increasing H, but the values of B will be higher for the same value of H than those on the ascending curve. When H is reduced to zero again, B has still a considerable value, i.e., about 11,000. There is thus within the iron a considerable amount of residual magnetism. If now H is increased in a reverse direction, B may be brought to zero, and, on still further increase of H, begins to increase in the other direction; i.e., the lines of force now pass through the iron in the opposite direction. The value of H which is required to reduce the residual magnetism, i.e., to bring B to the zero value, is called the coercive force. When H is increased in the reverse direction, the induction B traces the same form of curve as during the original ascent of H; that is to say, it increases rapidly for low values of H and then gradually approaches the region of saturation. If H is now decreased again, there is found to be a residual magnetism of about the same amount, but of opposite sign to that before found. If H is now increased in the same direction as at the starting of the process, the residual induction is reduced to zero only by a definite positive value of H. A further increase of H results in the rapid increase of B, and the curve finally merges into the original ascending curve. If now the same cycle of processes be gone through, the induction will traverse the same paths. The cycle then forms a closed curve of definite area. If at any point in the curve, such as the point C, H be decreased, B does not decrease over the path of increase, but tends to hold its value, or *lags* behind the change in H. On increasing H again the lower part of loop C is formed, and on further increase the path joins the original curve. This tendency of B to hold its value, or to lag behind H and so to form closed loops, is called *hysteresis*. When iron is carried through the hysteresis cycle, there is a loss of energy due to molecular friction and work done against other molecular forces consequent upon the reversal of direction of magnetization. This energy loss is manifested in a heating of the iron. It may be shown that this loss in ergs per cycle is proportional to the area of the hysteresis curve.

The magnetic properties of iron vary widely for different specimens. These variations depend, in the first place, on the past history of the material; that is to say, whether it has been annealed, hardened, stretched, twisted, or subjected to any treatment which would be likely to affect the molecular structure. In the second place, they depend on the chemical composition; that is to say, the presence or absence of such substances as manganese, carbon, etc. In general it may be stated that the softer the iron the greater the values of B and μ which may be obtained. The curve A (Fig. 1) is taken from a test on an average specimen of good soft iron. The maximum value of B is about 15,000, the maximum μ about 245, corresponding to $H = 4.5$. The whole curve in this case is unusually narrow and therefore incloses a small area, showing that in soft iron B follows H with greater readiness than in harder specimens, and that the loss due to hysteresis is smaller. When subjected to a magnetizing force, the behavior of soft iron is particularly sensitive to any kind of mechanical disturbance. Thus, if the specimen be lightly tapped while any given value of *H* is applied, the corresponding value of *B* may be largely increased. It retains considerable residual magnetism if undisturbed, but this residual practically disappears if the iron is tapped or heated, or the molecular structure is disturbed in any way. If soft iron is mechanically hardened in any way, that is to say, if it is hammered, rolled, stretched, or twisted, its permeability and value of residual magnetism are much lessened, and the coercive force is increased.

If, while the iron is on the descending part of the hysteresis curve and so has the higher value of *B* for any given value of *H*, an electric oscillation is caused to pass through a coil surrounding the specimen, it is found that the value of *B* drops suddenly to the lower value, i.e., the value on the ascending part of the curve. The electric oscillation sets up a molecular disturbance. This fact is made use of in the magnetic detector used in wireless telegraphy. The sudden decrease in induction is used to induce an electric impulse in an auxiliary circuit containing a telephone. The effect of hardening is shown in curve *D* (Fig. 1), which is taken from a test on the same sample of iron which gave the curve *A* after it had been subjected to a hardening process of rolling and stretching. It will be noticed that the maximum values of *B* are lessened, the permeability is less throughout, the residual magnetism is less, the coercive force greater, and the area of the closed curve appreciably larger.

When iron is subjected to such mechanical treatments as those mentioned above, and to annealing, hardening by quenching, tempering, etc., the various resulting grades of steel have widely different magnetic qualities aside from those due to differences in chemical composition. Speaking generally, a mild or soft steel is also magnetically soft; that is to say, μ is high and the coercive force low. The harder the steel the greater its magnetic hardness. This has been already illustrated in the two curves given above. If two samples of steel differ in the amounts of carbon contained in them, the one having the greater amount is both mechanically and magnetically the harder, the permeability is lower, the coercive force higher. For this reason permanent magnets are made of steel. Also a specimen hardened by tempering is found to be much harder than one of the same chemical composition which has been annealed.

Other substances than carbon affect the magnetic quality of iron, sometimes very greatly; chromium and tungsten increase the coercive force tremendously. For this reason tungsten is generally used in magnet steel. The coercive force in soft iron is about 2, while that in tungsten steel may exceed 50. Cast iron reaches a somewhat lower magnetization than wrought iron or steel, even for high values of *H*. When saturated, *B* is about three-quarters of the best values in iron. For moderate values of *H* in permeability and coercive force it generally resembles mild steel.

In certain alloys of iron there is a marked absence of magnetic quality. The presence of manganese in large quantities is particularly detrimental. Thus, in manganese steel, which contains about 12 per cent of manganese and 1 per cent of carbon, the permeability is only about 1.4 and is fairly constant in weak and strong fields; also there is practically no residual magnetism. Nickel steel is also most remarkable. A specimen containing 25 per cent of nickel was found to be practically nonmagnetic under ordinary conditions of temperature, its permeability being practically constant at 1.4. Thus, we have an alloy of two metals, each itself strongly magnetic, which has a practical absence of all magnetic quality. This alloy is also interesting in the further fact that when cooled to very low temperatures it becomes strongly magnetic and remains so after the temperature rises to ordinary values.

The effect of increase of temperature generally is to increase the magnetic properties of iron when the magnetizing force is low. This increase continues up to a temperature of 775° C., and beyond this temperature the iron suddenly becomes practically nonmagnetic. This temperature is known as the critical temperature of magnetization, and the evidence is plentiful from other facts that there is a decided molecular change in the structure of the iron at this point. For instance, this is the region known as the point of recalescence in the cooling of iron from white heat. The suddenness of this loss of magnetic quality with temperature is less as the magnetizing force is greater, and for large values of *H* it may even happen that the permeability decreases with increase of temperature.

We have seen that the area of the loop of hysteresis represents a loss of energy. This fact is of no special importance if the magnetization is constant and in one direction; but if the magnetization varies, or if it reverses many times per second, as is frequently the case in electrical apparatus, this loss may be quite appreciable. Thus, in the magnetic circuits of dynamo-electric machines the magnetization in the fields is always in one direction, and hence wrought iron of high permeability is used. In the armatures, however, and in alternating current apparatus in which the induction rapidly changes direction, the loss may be quite great, and it directly affects the efficiency of the machine. (See DYNAMO-ELECTRIC MACHINERY.) Hence, in these latter cases, the iron is worked at lower induction and must be soft so as to give a narrow hysteresis curve. Steinmetz has expressed a convenient law for this loss. It is stated in the formula $W = \eta B^{1.6}$. *W* is the loss in ergs per cycle, *B* is the maximum induction, and η is a constant of the material; η varies from 0.00124 to 0.0055 and for good annealed iron has an average value of 0.0033. It may be as high as 0.015 for steel and 0.08 for tungsten and manganese steel. Thus, at 60 cycles per second if

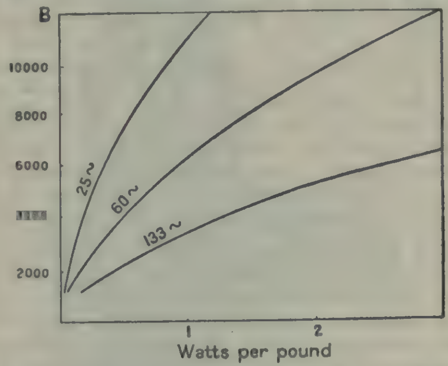

FIG. 3. CURVES SHOWING LOSSES OF ENERGY IN IRON.

the induction be 6000, for $\eta = 0.0033$ the loss in 100 cubic centimeters would be 2.1×10^7 ergs per second, or 2.1 watts. Closely allied with the hysteresis loss for alternating magnetization is the so-called Foucault or eddy-current loss. When the induction alternates, it induces currents in numerous little closed paths in the body of the iron due to its electrical conductivity. These currents therefore cause a loss of energy. To diminish these losses the iron is laminated so as to cut down the number of closed circuits in the body of the iron. In measuring iron losses due to alternating magnetization it is very difficult to separate these losses. In practice they are measured together, and the curves shown in Fig. 3 give the loss per pound of good soft sheet steel 0.011 inch thick at different inductions for 25, 60, and 133 cycles per second. See HEUSLER ALLOYS.

MAGNETISM, ANIMAL. See HYPNOTISM.

MAGNETISM, TERRESTRIAL. See TERRESTRIAL MAGNETISM.

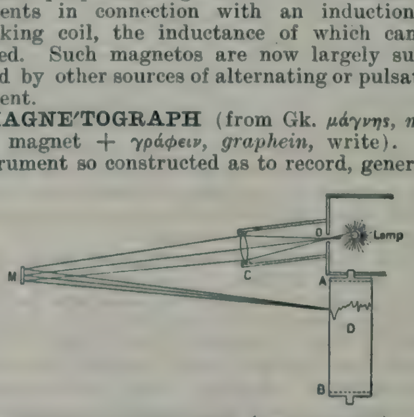
MAG′NETITE, or MAGNETIC IRON ORE. An oxide of iron (Fe_3O_4) containing 72.4 per cent metallic iron. It has an iron-black color, bright to dull metallic lustre, hardness of from 5.5 to 6.5 on the mineral scale, and a specific gravity of from 5.17 to 5.18. The crystalline form is isometric, commonly octahedra and dodecahedra, but it also occurs massive and in granular aggregates. Magnetite is readily distinguished from other iron-ore minerals by its strong magnetic properties; and in some cases it also exhibits polarity, being then known as loadstone. It is difficultly fusible (1225° C.), and in a strong oxidizing flame changes to the red oxide, Fe_2O_3, with loss of magnetism. Magnetite is found in many igneous rocks, in which it represents one of the earlier products of crystallization, and, in such, magmatic segregation (see ORE DEPOSITS) may concentrate the magnetite into workable deposits. Magnetite is also found in metamorphic rocks, in which it represents the product of either regional or contact-metamorphism. Some sedimentary rocks also contain it. The value of magnetite as an ore of iron depends in part on the percentage of sulphur, phosphorus, and titanium which the ore contains, and in part on siliceous mineral impurities, but the latter can be eliminated by magnetic separation. See ORE DRESSING.

Magnetite deposits may serve as important sources of iron. In the United States it is known to occur along the Appalachians, especially in the Adirondacks, in the Highlands of New York and New Jersey, at South Mountain, Pa., and in Virginia and North Carolina. Only the first-named is of great commercial importance. It is usually associated with pre-Cambrian gneisses. Deposits of magnetite are also known in Minnesota, Missouri, Colorado, Utah, California, and in foreign countries. The deposits of Kirunavaara and Gellivare in Sweden are the largest known deposits in the world. The production of magnetite in the United States in 1913 was 2,375,274 long tons. Consult: H. Ries, *Economic Geology* (3d ed., New York, 1910); Waldemar Lindgren, *Mineral Deposits* (ib., 1913); Singewald, *Titaniferous Iron Ores* (Washington, 1913). See IRON.

MAGNETO, măg′nĕt-ō *or* măg-nē′tō, IN MOTOR VEHICLE. See MOTOR VEHICLE.

MAGNETO-ELECTRIC MACHINE. A machine for generating electricity by rotating a coil of wire in the field of a permanent magnet, usually of the horseshoe type. The rotating coil is commonly wound on a soft-iron core to increase the density of the magnetic field. The fundamental principle on which the machine operates will be found described under DYNAMO-ELECTRIC MACHINERY. Magneto machines are used for a variety of purposes where it is desirable to use alternating currents. For blasting operations such a generator is arranged with a rack and pinion attached to the armature, which, when rapidly rotated, develops a current which, conducted through insulated wires, heats a platinum wire and explodes the charge by means of a fulminate cap. Telephone circuits not operated on the "common battery" system usually employ magneto generators for ringing. (See TELEPHONE.) One of the largest fields of use of the magneto is that of furnishing ignition currents for gas and oil engines of small and medium sizes. For automobile-engine ignition the generator is driven by gears from the main shaft of the motor, and for motor-boat installations by gears, chain and sprocket, or by frictional contact with the flywheel. (See INTERNAL-COMBUSTION ENGINE; MOTOR VEHICLE.) To a limited extent magnetos are employed for medical purposes, to generate small alternating currents in connection with an induction or shocking coil, the inductance of which can be varied. Such magnetos are now largely superseded by other sources of alternating or pulsatory current.

MAGNE′TOGRAPH (from Gk. *μάγνης, magnēs,* magnet + *γράφειν, graphein,* write). An instrument so constructed as to record, generally by photographic means, the variations or fluctuations to which the earth's magnetism is continually subject. The action of such an instrument is shown by the accompanying sketch. Such instruments, as generally arranged, give a continuous record of the changes in the magnetic declination and in the strength of the



RECORDING MAGNETOMETER (MAGNETOGRAPH).

The light from the lamp, shining through the small opening *O* upon the lens *C*, is brought to an image of *O* upon the sensitive paper on the drum *D*, after being reflected from the magnetometer mirror *M*. Any angular motion of *M* around a vertical axis causes the image to move with reference to *A* and *B*. This motion, combined with that of the drum *D* as it is revolved by clockwork, gives a broken line as the record of the magnetic fluctuations.

horizontal and of the vertical components of the earth's magnetic field. They will be found in use at magnetic observatories. See MAGNETOMETER; TERRESTRIAL MAGNETISM.

MAG′NETOM′ETER (from Gk. μάγνης, *magnēs*, magnet + μέτρον, *metron*, measure). An instrument for measuring the strength of a magnetic field, more specifically of the earth's magnetic field, in which case the instrument is also generally capable of measuring the magnetic declination, or inclination, or both, according to mode of construction. It may be a simple small magnetic needle supported upon a point and swinging over a divided circle, or it may be a magnetized bar hanging upon a fibre of silk or quartz or other material, and the deflections read with a mirror on the magnet and using a telescope and scale or a reflected beam of light In a simple magnetometer the magnet hangs in a small house or box of wood or copper and the attached mirror is visible through a little window. The magnet and mirror are suspended upon the silk or quartz fibre, or phosphor-bronze ribbon, hanging in the tube above the magnet house. Fig. 1 shows an early form of the "tangent" magnetometer with the attached bar for supporting the deflecting magnet, which is placed at a definite distance from the suspended or deflected magnet, and with its axis pointing at right angles to the compass direction or magnetic meridian.

A magnetometer set up with its magnet in the magnetic meridian will show the declination (q.v.) and its variations; i.e., the angle may be found between the magnetic north as shown by the magnet and the true north as determined by astronomical observations. By observing the time required for a complete vibration of the suspended magnet a measure of the relative strength of the earth's magnetic field is obtained. From a combination of vibration and deflection observations the absolute strength of the field is found. When the magnet is supported, e.g., on two fibres, as in Fig. 2, then the instrument is so set up that the bifilar suspension holds the magnet at right angles to the magnetic meridian. In this position this magnetometer measures the strength of the horizontal component of the earth's magnetic field.

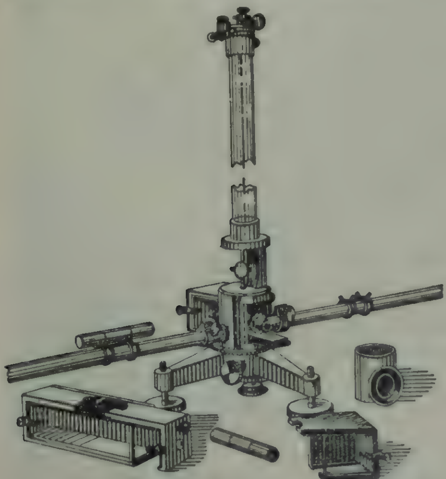


FIG. 1. GAUSS-WEBER TANGENT MAGNETOMETER.

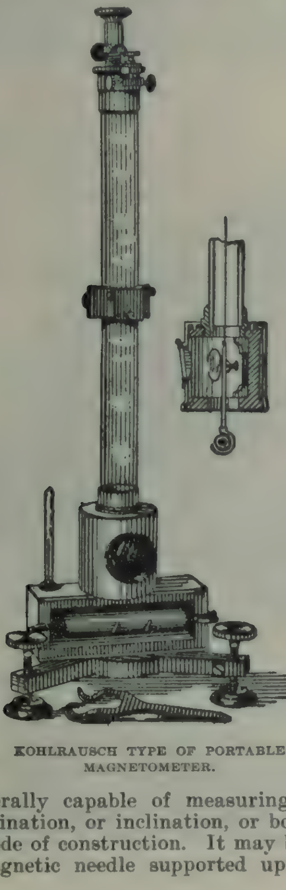

FIG. 2. KOHLRAUSCH TYPE OF PORTABLE BIFILAR MAGNETOMETER.

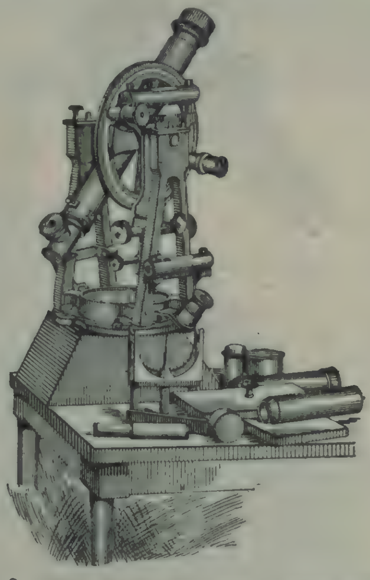

FIG. 3. THEODOLITE FOR MAGNETIC OBSERVATIONS.

Figs. 3 and 4 show a theodolite used for the determination of the astronomical meridian, or true north, at a certain given station, and a standard form of "sine" magnetometer. Here the astronomical meridian is determined with the theodolite, which is then replaced on the mounting by the magnetometer. The chief difference between this form of magnetometer and that shown by Fig. 1 is that here during deflection observations the axis of the deflecting magnet is always supposed to be at right angles to that of the deflected magnet. The reader can find full descriptions of magnetometers in the bulletins of the Division of Terrestrial Magnetism of the United States Coast and Geodetic Survey and in the issues of *Terrestrial Magnetism* (Baltimore, current). The older forms of magnetic instruments will be found described in the larger treatises on physics, while the simple apparatus is discussed briefly in Thompson, *Elementary Lessons in Electricity and Magnetism* (see latest ed., New York). Brief references to the newest types of magnetic instruments as devised by the Department of Terrestrial Magnetism of the Carnegie Institution of Washington, for use in magnetic surveys on land and at sea, will be found in the article Terrestrial Magnetism. See also Declinometer; Dip Circle; Magnetograph.

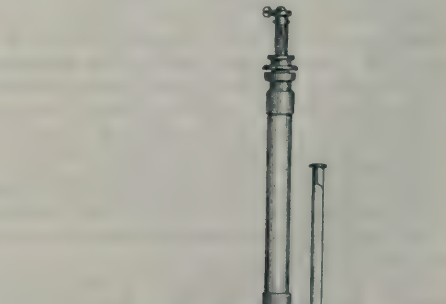

FIG. 4. UNITED STATES COAST AND GEODETIC SURVEY PORTABLE SINE MAGNETOMETER.

MAGNIF'ICAT (Lat. *Magnificat anima mea Dominum,* My soul doth magnify the Lord). The song of thanksgiving ascribed to the Virgin Mary (see Luke i. 46–55), and later incorporated into the service of vespers, in which it forms the principal part, corresponding to the other "evangelical canticle," the *Benedictus,* at lauds. At solemn vespers, during the singing of the *Magnificat,* the altar is censed by the officiant, vested in a cope. The English version was incorporated in the Anglican prayer book, to be sung or said after the first lesson at evening prayer. It was omitted in the American prayer book, but restored at the revision.

MAG'NITUDE (Lat. *magnitudo,* from *magnus,* great), Perception of. Size or magnitude, psychologically regarded, is a quantitative determination of extension. For its perception, see Extension, and the perceptions of Form, Distance or Depth, Locality, and Movement.

MAGNO'LIA. A city and the county seat of Columbia Co., Ark., 150 miles southwest of Little Rock, on the St. Louis Southwestern Railroad, and the terminus of the Louisiana and Northwest Railroad (Map: Arkansas, B 4). It is the centre of a fertile region, having valuable timber lands, and carries on a trade in cotton, cottonseed products, potatoes, oats, corn, fruit, and lumber, its commercial interests being of considerable importance. A State agricultural college is situated here. Pop., 1900, 1614; 1910, 2045.

MAGNOLIA (Neo-Lat., named in honor of Pierre Magnol, a French botanist of the early seventeenth century). A genus of large-leaved beautiful trees of the family Magnoliaceæ, with large solitary flowers, having a calyx of three sepals, a corolla of six to 12 petals, and carpels arranged in cones. The species are natives chiefly of North America, the Himalaya Mountains, China, and Japan. The wood is in general soft, spongy, and of little value. *Magnolia fœtida,* or *Magnolia grandiflora,* sometimes called the big laurel, is a lofty and magnificent evergreen, rendered conspicuous at a great distance by its white flowers nearly a foot in diameter. It is found in the coastal plain from North Carolina to central Florida and Louisiana, where it is conspicuous in the forests. *Magnolia tripetala* is found on the Alleghany Mountains, and extends as far north as lat. 43°. From the radiated manner in which its leaves are disposed at the extremities of the branches it is called umbrella tree. It has very large white flowers. *Magnolia acuminata,* cucumber tree, inhabits the same districts, and is a lofty tree with greenish-yellow flowers, which are less admired than those of other species. *Magnolia virginiana,* white bay, beaverwood, swamp sassafras, a native of Pennsylvania, Virginia, and Carolina, is a tree or shrub of three to 75 feet in height, with beautiful fragrant white flowers. The yulan, or Chinese magnolia (*Magnolia yulan*), has been much cultivated in China for more than 1200 years, for its profuse, beautiful, fragrant white flowers, which appear before the deciduous leaves. It is one of the finest of ornamental trees, and

MAGNOLIA VIRGINIANA.

MAGNOLIA AND MANGROVE

1. MAGNOLIA (Magnolia Soulangiana).   2. MANGROVE (Rhizophora Mangle).

succeeds in most of the United States from New York southward. It is followed in time of flowering by *Magnolia soulangeana* and *Magnolia obovata*, a Japanese species with purplish tinted flowers. *Magnolia macrophylla* and *Magnolia fraseri*, American species, have about the same range as *Magnolia fœtida*, are trees 40 to 50 feet in height, and are conspicuous for the size of their leaves, which in *Magnolia macrophylla* become from 1 foot to 3 feet long and a foot across. The flowers are white with a purple spot at base, the petals 3 to 6 inches long. The genus *Magnolia* appears first in the Cretaceous rocks of Europe, and its fruits and leaves are abundant in the succeeding Tertiary deposits of North America, Europe, Asia, and Australia, and also in the Arctic regions far outside the limits of its present distribution. Consult W. E. Maneval, *Development of Magnolia and Liriodendron* (Baltimore, 1914).

MAG′NUS. The name of several kings of Norway, Denmark, or Sweden.—Magnus I (Olafsson) the Good, King of Norway (1035–47) and of Denmark (1042–47), was a son of St. Olaf (q.v.).—Magnus Haraldsson, son of Harald Haardraade, was King of Norway (1066–69).—Magnus II the Barefooted, King of Norway (1093–1103), conquered the Orkneys and Hebrides, and was killed in an expedition to Ireland.—Magnus the Blind was King of Norway (1130–35).—Magnus Erlingsson, King of Norway (1161–84), was the first King to be crowned in Scandinavia.—Magnus Lagaböter, King of Norway (1263–80), was the great reformer of the laws of Norway, Iceland, the Faroe Islands, and Greenland.—Magnus Ladulås, King of Sweden (1275–90), was a just ruler, who protected the people against the powerful nobles.—Magnus Eriksson was King of Norway (1319–55) and of Sweden (1319–64). He gave Norway to his three-year-old son Haakon in 1343. He reigned in Sweden until 1364, when he was deposed by his subjects, who gave the crown to Albert of Mecklenburg. Magnus was drowned in 1374.

MAGNUS, Heinrich Gustav (1802–70). A German physicist and chemist, born at Berlin. He studied at Berlin and under Berzelius at Stockholm. At the age of 26 he had already made important contributions to chemistry, and in 1834 was made extraordinary, and in 1845 full, professor of physics and technology in the University of Berlin. His original investigations include important experiments on the transmission of heat through gases, a series of determinations of the vapor pressures of water at different temperatures, and of the vapor pressures of homogeneous liquid mixtures, etc. Consult Hofmann, *Zur Erinnerung an Gustav Magnus* (Berlin, 1871).

MAGNUS, Olaus (1490–1558). A Swedish historian and cartographer, born at Linköping. Following the lead of his elder brother, the Archbishop of Upsala, he entered the Church, and was an archdeacon by 1523. On the success of the Reformation in Sweden both brothers went to live in Rome, and upon the death of the Archbishop (1544) Olaus became his titular successor. Two years afterward Paul III sent him to the Council of Trent. His *Historia de Gentibus Septentrionalibus* (22 vols., Rome, 1555; numerous editions in Latin, Italian, French, German, Dutch, English, and Swedish) is a valuable description of the customs and mode of living of the contemporaneous people of the North, their animals and plants. His large map of Scandinavia (Venice, 1539) is a work of great merit. Consult O. Brenner, *Die echte Karte des O. Magnus vom Jahre 1539* (Christiania, 1886).

MAGNUS, Sir Philip (1842–). An English educator. He was born in London and was educated at University College, London. He organized the City and Guilds of London Institute and was its secretary in 1880–88. For his work in general education and particularly in technical education—he was member of the royal commission on that subject in 1881–84—he was knighted in 1886. In 1906 he was elected member of Parliament for London University. In 1907 he was president of the education section of the British Association. He wrote *Industrial Education* (1888) and textbooks of mechanics.

MAGNUS HITCH. See Knotting and Splicing.

MAGNÚSSON, mȧg′nōōs-sôn, Arni (1663–1730). A Norse scholar and antiquary, born in Iceland, a descendant of Snorri Sturluson. After studying at home Magnússon went to Copenhagen, where he soon after received an appointment in the Royal Archives. In 1701 he became professor of philosophy and northern antiquities at the university. From 1702 till 1712 he traveled through Iceland as a member of a commission that gathered old manuscripts, and at this time laid the foundation of the famous collection that bears his name, *Den Arnamagnœanske Haandskriftsamling*, which contains over 15,000 old manuscripts and books from Iceland, Norway, and Denmark. It is largely owing to Magnússon's industry and enthusiasm that so much of the classical literature of Iceland has been preserved. After returning to Denmark he continued to add to his collection. In 1728 a part of his collection was destroyed by fire. The remaining portion, together with Magnússon's whole fortune, was bequeathed to the university library, where it is now lodged. A complete catalogue of the collection, with a biography of Magnússon and other related matter, was published by Dr. Kr. Kaalund (2 vols., Copenhagen, 1888–94).

MAGNÚSSON, Eiríkr (1833–1913). An Icelandic scholar. He was born at Berufjördur, Iceland; was educated in theology at the Latin School of Reykjavik; and in 1862–66 edited a revised edition of the Icelandic Bible. From 1871 to 1910 he was underlibrarian at Cambridge University, where he lectured also on Iceland. He did much to promote the study of Old Norse literature, in which he was a scholar of the first rank. In 1893 he was awarded a gold medal by the Société des Inventeurs, Paris, for the plan of a library building which could be extended indefinitely. He translated from Icelandic many sagas and six stories under the title *Three Northern Love Stories and Other Tales* (1875).

MAGNÚSSON, Finnur (Magnusen, Finn) (1781–1847). A Norse scholar and archæologist. He was born Aug. 27, 1781, at Skálholt in Iceland. He practiced law, but his strong bent towards archæological pursuits led him in 1812 to return to Copenhagen, where he devoted himself with much zeal to his favorite studies, under the direction of his distinguished countrymen Thorkelin and Thorlacius. In 1815 he obtained a chair of literature in the university. Among his earliest and most noteworthy works are his papers on the aboriginal home and earliest migrations of the Caucasian races (1818); his contributions to northern archæology (1820); the indexes, glossaries, and lexicon which he compiled for the elucidation of the second and third of the Arni Magnússon editions of the Eddas (1818 and 1828); his comprehensive translation of the Elder Edda, *Ældre Edda, oversat og forklaret* (1824); and his exposition of the same work (*Eddalæren og dens Oprindelse*, 1824–26). Among his later works, his *Runamo og Runerne* (1841) has given rise to much angry discussion; and although many of his interpretations of assumed runes have been proved to be untenable, the learning and acumen which he brought to bear on the subject of runes generally have thrown great light on this branch of archæology. In conjunction with Rafn, Magnússon elucidated the history and antiquities of Greenland in an able work (*Grönlands historiske Mindesmærker*, 3 vols., 1838–45), his best work; and he subsequently prosecuted a similar course of inquiry in regard to Russia in *Antiquités russes* (1850–52). In addition to these works, Magnússon annotated many of the most important remains of old northern literature, as the *Heimskringla, Hákonarmál, Laxdæla-Saga*, etc.; and besides numerous monographs on archæological and historic subjects of interest, made many valuable contributions to current Icelandic literature. He died Dec. 24, 1847.

MA′GO (Lat., from Gk. *Μάγων, Magōn*). A name common in Carthaginian history. 1. The most famous of those who bore it was Mago, the son of Hamilcar Barca, and younger brother of Hannibal. He participated in the invasion of Italy. After the battle of Cannæ, under orders from the government at Carthage, he opposed the Roman armies in Spain for many years. In 207 he was defeated by Scipio Africanus Maior, at Silpia. In 206 B.C. he crossed over into Liguria in Italy, but was defeated in a battle there by the Romans (see CETHEGUS, 1), and on the way home died of his wounds (203 B.C.). Consult: Konrad Lehmann, *Der Angriff der drei Barkiden auf Italien* (Leipzig, 1905); Otto Meltzer, *Geschichte der Carthager*, vol. iii (Berlin, 1913). 2. The reputed author of a famous work on agriculture, which was brought to Rome, by order of the Senate, after the destruction of Carthage, and translated into Latin. 3. The name was borne also by a Carthaginian who was famous as organizer, especially of the Carthaginian army, who flourished about 550–500 B.C.

MAGOF′FIN, BERIAH (1815–85). An American politician, born in Harrodsburg, Ky. He graduated at Centre College, Danville, Ky., in 1835, and at the law school of Transylvania University in 1838, after which he began to practice at Jackson, Miss. In 1859 he was elected Governor for a four years' term. He was a strong advocate of the "Crittenden compromise." He refused to pay any attention to Lincoln's first call for troops, and followed his refusal by proclamations prohibiting recruiting in Kentucky for either Federal or Confederate armies. In the spring of 1862 the State Legislature passed a resolution over his veto asking him to issue a proclamation against the entrance into the State of Confederate troops. He complied, but in the following August, recognizing that his position was untenable and his power gone, he called the Legislature in special session and resigned. He was a member of the State Legislature for several terms after the war.

MA′GOG. See GOG AND MAGOG.

MAGOG. A town of Stanstead Co., Quebec, Canada, at the outlet of the river of the same name from the north end of Lake Memphremagog, 19 miles southwest of Sherbrooke (Map: Quebec, F 5). It is a favorite angling resort, has daily steamer communication with Vermont, and is a station on the Canadian Pacific Railway. Its manufactures include lumber, butter and cheese, and textile prints. Pop., 1901, 3516; 1911, 3978.

MAGOON, ma-gōōn′, CHARLES E. (1861–1920). An American lawyer and administrator, born in Steele Co., Minn., and educated at the University of Nebraska. He was admitted to the bar in 1882, became judge advocate of the Nebraska National Guard, was law officer of the Bureau of Insular Affairs, War Department, in 1899–1904, general counsel of the Isthmian Canal Commission for a year, and a member of the commission (1905–06). From May 25, 1905, to Oct. 12, 1906, he was governor of the Canal Zone, and during most of this period was also Minister to Panama. During the military occupation and intervention of the United States in Cuba from 1906 to 1909, consequent upon the revolution in the island, Magoon was governor representing the War Department. In this capacity he maintained order, fostered prosperity, and introduced many beneficial reforms in finances and sanitation. He published *The Law of Civil Government under Military Occupation* (1902).

MAGOT, măg′ot *or* mȧ′gō′. The Barbary ape. See MACAQUE.

MAGPIE (variant of *magotpie*, from *Mag, Magot*, abbreviation of *Margaret* + *pie*, OF., Fr. *pie*, from Lat. *pica*, magpie, either from *pingere*, to paint, in allusion to its spotted hue, or connected with *spicere*, to spy, and ultimately with provincial Eng. *speight*, woodpecker). Somewhat intermediate between jays and crows and closely related to both is the genus *Pica*, the species of which are known, wherever English is spoken, as magpies. In size and coloration magpies resemble small crows, while in many other respects they are more like the jays. Their most prominent external character is the long, graduated tail, which is sometimes longer than head and body together, and the outer feathers of which are scarcely half the length of the middle pair. The best-known species of the genus is the common magpie of Europe (*Pica pica*), of which a very closely allied form, known as the black-billed magpie (*Hudsonia*), is abundant in western North America, except California, ranging as far east as Manitoba and Minnesota, and northward to the North Saskatchewan River. (See Plate of JAYS, MAGPIES, ETC.) This bird is rather more than 15 inches long and about 2 feet across the extended wings. The color is lustrous black, with green, violet, and purple, sometimes even golden, iridescence. The lower parts, a patch on each shoulder, and portions of the wings are white. The bill and feet are black. A very similar species (*Pica nuttalli*) is found in California, but is easily distinguished by the bright yellow bill and naked space about the eye. Magpies generally go in pairs and are remarkable for their slyness and cunning in escaping observation. When in small flocks, they are bolder and more noisy. The cry is loud, harsh, and unmusical, but when the bird is alone it is usually silent. It is very clever in hunting and securing its food, which consists of almost anything eatable, though, like the jays, it is especially fond of eggs and young birds. On this account magpies are constantly hunted and killed by gamekeepers; but in many places these birds are encouraged to come about houses because of their bright, saucy habits and handsome plumage.

The nest of the magpie is a most remarkable structure, nearly as large as a bushel basket, placed in thick shrubbery. The top and outside are made up of interwoven thorny branches, within which is the nest proper, composed of earth and lined with fibres and grass. There is an opening on each side, so that the long tail rests in the one at which the bird enters, while it can when necessary escape at the other without turning. The eggs are from five to nine in number, pale drab, dotted, dashed, and blotched with purplish brown. The magpie is easily tamed and soon becomes very familiar and may sometimes be taught to articulate a few words, but, like the crow, it is a troublesome pet, for it is a sneak thief of the same stamp. In the Old World the common magpie occurs in Siberia as well as in most parts of Europe, and there are several other Asiatic members of the genus. The so-called blue magpies are natives of the Old World and belong to the genus *Cyanopolius*, but they are quite as much jays as magpies. There are only two species, which are very similar, though one is confined to the Spanish peninsula, while the other occurs in eastern Asia and Japan. The name blue magpie is also given sometimes to the very long-tailed jays of the genera *Calocitta* and *Urocissa*, the former a Central American, the latter an Oriental group. Various birds of pied plumage not magpies at all are sometimes called so, as the mottled owl, a magpie robin, magpie shrike, etc.

Consult: Elliott Coues, *Birds of the Northwest* (Washington, 1874) and the authorities there cited; L. S. Keyser, *Birds of the Rockies* (Chicago, 1902); Dawson and Bowles, *The Birds of Washington* (Seattle, 1909).

MAGRATH, mȧ-grăth′, William (1838–). An Irish-American landscape and figure painter, born in Cork. He studied in his native city before coming to the United States in 1855. Afterward he practiced in London, in New York City, where he was elected a National Academician in 1876, and in Washington. His best work is in character studies, such as "The Road to Kenmair" (1871); "The Reveille" (1873); "Rustic Courtship" (1877); "On the Old Sod" (1879), in the Metropolitan Museum of Art, New York; "Paddy on his own Land" (1900); "Sheep Pasture" (1903); "The Killarney Country" (1910); "The Bog of Allen, Ireland" (1911); "Bog Lands" (1913).

MAGRU′DER, John Bankhead (1810–71). An American soldier, born at Winchester, Va. He graduated at West Point in 1830 and was assigned to the Seventh Infantry, but was transferred the next year to the artillery. He served at various Eastern garrisons, became first lieutenant in 1836, took part in the Florida War of 1837–38 and in the military occupation of Texas in 1845–46, and in 1846 was promoted to be a captain. During the Mexican War he was brevetted major (April, 1847) and lieutenant colonel (September, 1847) for gallantry at Cerro Gordo and Chapultepec respectively. He was in garrison in Washington in 1861, and resigned from the national service to become colonel in the Confederate army. His first command was that of the artillery around Richmond. After winning the battle of Big Bethel he was promoted to be brigadier general in June and became major general in October. While in command of the district of Yorktown he prepared the fortifications across the peninsula of Yorktown, and with 12,000 men defended a line 13 miles long against McClellan's entire army during the month of April, 1862. In the Seven Days' Battles he commanded the Confederate left wing and attacked at Savage's Station and Malvern Hill. He was then appointed to the new Trans-Mississippi Department, but this command was reduced to Texas alone. On Jan. 1, 1863, he recaptured Galveston, drove off the blockading squadron, and succeeded in keeping the port open. New Mexico and Arizona were added to his department. At the close of the war he joined the army of Maximilian in Mexico as major general and served until the Empire fell. For a time he lectured on his experiences in Mexico, but settled at Houston, Texas, in 1869.

MAGUAQUE, Rodrigo Cota de. See Cota de Maguaque, Rodrigo.

MAGUEY, măg′wā; *Sp. pron.* mȧ-gā′ė. Various agaves and their fibre, more properly restricted to *Agave cantala*, the Mȧnila maguey. See Agave.

MAGUIRE, mȧ-gwīr′, John Francis (1815–72). An Irish lawyer and journalist. He was called to the bar in 1843, edited and published at Cork the Roman Catholic *Examiner*, sat in Parliament as member for Dungarvan from 1852 to 1865 and for Cork from 1865 till his death. He was a supporter of Home Rule, and was for several years mayor of Cork. He was the author of *The Industrial Movement in Ireland* (1852); *Rome and Its Ruler* (1857; enlarged as *The Pontificate of Pius IX*, 1870); *Father Mathew: A Biography* (1863); *The Irish in America* (1868); *The Next Generation* (1871).

MAGUS, Simon. See Simon Magus.

MAGYAR, mŏ′dyŏr, László (1817–64). An Hungarian traveler, born at Maria-Theresiopel (Szabadka). He was in the Austrian navy for two years and from 1844 to 1847 traveled in the United States, the West Indies, and South America, where he fought with Argentina against Uruguay. Subsequently he visited the Portuguese colonies of South Africa, journeying thence by caravan into the centre of the continent as far as Bihe, where he married a native princess and remained to make important explorations into the surrounding unknown country. In 1857 he left for Luiera Bay to establish a post between Benguela and Mossamedes for the Portuguese government. The results of his travels were published at Budapest (1859) under the title, *Travels in South Africa in 1849–57*.

MAGYAR LANGUAGE. See Hungarian Language.

MAGYAR (Gypsy, or Hungarian) **MUSIC**. The characteristic music of Hungary, in which the Magyar and Gypsy elements in the population find expression. The following characteristic scale is undoubtedly of Asiatic origin: C, D, E♭, F♯, G, A♭, B, C. The distinctive features of Magyar music are endless variety of rhythm, absolute freedom, even abruptness, in modulation, and a profusion of embellishments. Polyphony is practically unknown, the performances consisting chiefly of improvisations upon well-known melodies, although original themes are also employed. The national instrument is the violin. The Magyar orchestra was formerly composed of various instruments, the violin and the cembalo being the principal ones. This cembalo is an oblong box with steel strings struck by two wooden mallets. To-day there are also second violins, celli, double basses, clarinets, and trumpets. These, however, are not used as in our music, but only for the doubling of the harmonies and the accentuation of the rhythm. The principal instrument always remains the violin, and all others follow it. It is almost impossible for us to conceive how so many performers can keep together when the principal instrument practically improvises. But competent musicians who have heard the Magyar orchestra are unanimous in their admiration of the precision and fire with which everything is executed. Even as early as the thirteenth century the musicians of Hungary were famous. During the fourteenth century their assistance was considered indispensable in the celebration of all public festivals. It is on record that about 1550 Karmann reaped honors and wealth through his marvelous performance upon the violin. Michael Barum is called the Hungarian Orpheus. He won the first prize at a tournament arranged by the magnates of Hungary. About 1775 Cinska Pama was regarded as the greatest violinist. The more recent of the great Magyar violinists, who also appeared in Germany, were Paticarius, Kecskeméty, Sarközy, and Bihary.

That practically nothing has been preserved of their compositions is due to the fact that they were chiefly improvisations. The peculiar embellishments, the sudden transitions, and ever-changing and complicated rhythms make actual notation exceedingly difficult. Nevertheless, the written works of Lavotta and Czermak give a good idea of the genuine Magyar music. The latter is regarded by the Hungarians as their greatest national composer, although by birth he was a Bohemian.

The musical forms of the Hungarians are very limited. The artists give themselves up to momentary inspirations. Hence the chief form would be the fantasia, which, in reality, is no form at all. The only definite artistic form we find in the national dance, the csárdás (q.v.). Some of our great masters have been strongly influenced by the Magyar music, as Haydn, Schubert, Joachim, Brahms, and particularly Liszt, whose 15 Hungarian rhapsodies are masterly arrangements of genuine Hungarian melodies. The great pianist has also written a book, *Des Bohémiens et de leur musique en Hongrie* (Paris, 1859), translated into German by P. Cornelius, *Die Zigeuner und ihre Musik in Ungarn* (Budapest, 1861). Consult also the Appendix to Ludwig Nohl's *Allgemeine Musikgeschichte* (Leipzig, 1884), and D. C. Parker, *Some Aspects of Gypsy Music* (New York, 1913).

MAGYARS. See HUNGARY.

MAHABHARATA, mȧ-hä'b'hä'rȧ-tȧ (Skt. *mahā*, great + *bhārata*, war or story of the Bharatas). The great epic of India, nearly eight times as long as the *Iliad* and *Odyssey* combined. Native Hindu tradition interprets its title as referring either to the great war waged by the Bharatas or to the poem itself which recounts the war. The latter is probably a later view, based on the complete epic as it has come down to us in 18 books, containing altogether about 100,000 stanzas. Of these, some 5000 are in four-verse form of 11 syllables each (4 × 11), and the remainder, with the exception of about 200 stanzas of more elaborate construction, in stanzas of 30 syllables. There are also short passages in prose. An improbable tradition represents this poem as having been originally much longer. More in accord with historic possibility is another tradition pointing to the fact that the Bharata poem was at first only a quarter of its present length, the poem itself being distinguished from the numerous episodes now included in it. The predicate *Mahā* ('great') would thus distinguish the redaction containing these episodes from one without them. A supplementary book on the genealogy of Vishnu, the *Harivanśa* (q.v.), is a still later addition. Like many other Hindu works, the Mahabharata is supposed to have been composed by Vyāsa; but in reality it bears the marks of having been compiled by numerous revisers working over the material of the old rhapsodists and uniting this with the lucubrations of sectarian religious philosophers. The kernel of this work is an epic narrative telling how the ancient family of the Kurus (Kauravas) was overthrown, in consequence of their own wickedness, by the opposed Panchalas and Pandus (Pandavas). The last named are the real heroes of the epic, which lauds them as faithful worshipers of the true god Krishna, the human incarnation of Vishnu (q.v.). After the genealogy of the families has been narrated in the first book, the epic action begins with an account of a gambling match, at which the Kurus unfairly cheated the Pandus (reported to be their cousins), robbed them of their neighboring kingdom, and exiled them for 12 years. The story of the exile in the woods gives opportunity for many tales, told to while away the tedium of the banishment. The most famous episodes are those of Nala and Damayanti and of Savitri. On the expiration of the exile period the opposing forces, having collected their allies, meet on the sacred Plain of the Kurus, and the great war (or 18 days' battle) takes place, resulting in the overthrow of the Kurus. Though the epic properly ends here, it is prolonged, by means of philosophical and ethical discussions embracing the most minute points of social and moral observance, for 20,000 stanzas, which have nothing to do with the story itself and are in fact merely a popular exposition and summary of legal and philosophic lore. These huge additions make of the epic an encyclopædia of all knowledge with a strong bias towards religious proselytism. As compared with the Ramayana (q.v.) (the second great epic of India), the Mahabharata is mentioned earlier in Hindu literature and the scene is laid in the older seat of Brahmanic learning, at Kurukshetra and Hastinapura (q.v.), near the modern Delhi. It is probably in origin the older of the two epics, though dating in its present form from a later period than the time when the Ramayana was composed. Some sort of a Bharata war story was probably handed down from remote antiquity in constantly changing poetic form; but the usurpation of the heroes' place by the newer house of the Pandus shows that our present version cannot be of very great antiquity, and it is likely that some of the episodes are really older than the main poem in its modern shape. The present poem appears to have been composed about 200 B.C., with extensive additions from time to time, till about 100 A.D., when it was probably almost in the condition now preserved to us, as was certainly the case 300 or 400 years later. Many later Puranas (see PURANA) are based on the story of this epic and are virtually sectarian tracts in honor of Vishnu or Siva, the two gods whose unity is proclaimed by the epic. Later classical literature also draws largely from the same source. Holtzmann's opinion that the epic dates from the Middle Ages is now given up by all scholars. Of late Dahlmann has contended that the epic was composed all at one time, perhaps even by one person, about 500 B.C. In this extreme form Dahlmann's views have proved unacceptable; though he has shown that it is not possible to reject offhand this or that portion as a later addition, and has thus put the finishing touch to the demolition of Holtzmann's theory of the construction of the poem. The composite character of the poem as shown by metre and contents has been strongly brought out by Hopkins, who argues against the extremist opinions of Dahlmann as regards both the date of the poem and its unity of composition. It is an open question whether in its earliest beginnings the Bharata poem did not record events of far greater historical importance than those now chronicled in it. Grierson holds that it originally described a conflict for the controlling power in all Northern India as waged by the earliest Aryan immigrants against those who came into the country at a later date. While it would be difficult to find support for this hypothesis in the poem itself, it is at least a reasonable theory. On the other hand, quite unsupported by any sound interpretation of history is the use made of supposed epic data by Hewitt in his recent Akkadian studies. Apart from the question of the date of the poem and of the war as now described in it, lies the question of the date of the original Bharata war, which may reasonably be referred to about the twelfth century B.C. According to Aiyer, B.C. 1194 is the date of the Kuru-Pandu battle, but this view, though ingeniously supported, ignores the fact that the Pandus were unknown at that early age. The prose portions of the epic seem to be based on an earlier work, the *Itihāsa-Purāṇa*, which purported to be an elucidation and supplement of the Vedic Itihāsa hymns (Skt. *Iti ha āsa*, Thus it was) and therefore constituted the link between the Veda and the epic.

The text of the Mahabharata in its Northern recension has been published in Calcutta in four quarto volumes (1834–39), to which is added a table of contents. A better edition is published in Bombay (1863) in six volumes, with one recently added containing the Harivanśa. It is stereotyped and has been reprinted several times (with the Harivanśa in 1900), and has besides the text the commentary of Nilakantha. An edition based on the Southern recension was published at Madras (1855–60) in four volumes. Extracts from the Southern version of the text (not radically different from the Northern) have been given by Winternitz (*Indian Antiquary*, vol. xxvii). English translations have been made by Mohan Ganguli (Calcutta, 1883–96) and M. N. Dutti (ib., 1895–1905). A new edition was begun at Calcutta in 1904 by Tarkaratna, and there is a French translation by Fauche and Ballin (Paris, 1870–99), which is neither complete nor accurate. Various episodes of the epic have been translated by Holtzmann, *Indische Sagen* (Stuttgart, 1854), and by Edwin Arnold, *Indian Idylls* (Boston, 1883). See also E. W. Hopkins, *India, Old and New* (New York, 1901). Summaries of the poem are furnished by Williams, *Indian Wisdom* (London, 1876); Romesh Dutt, *Mahabharata, the Epic of Ancient India, Condensed into English Verse* (ib., 1898); J. C. Oman, *The Great Indian Epics* (ib., 1899). For a study of the epic in connection with the Sanskrit literature, consult Moritz Winternitz, *Geschichte der indischen Literatur* (Leipzig, 1908 et seq.). Technical works are: Adolf Holtzmann, *Das Mahābhārata* (Kiel, 1892–95); J. G. Bühler, *Indian Studies* (Vienna, 1892); Joseph Dahlmann, *Das Mahābhārata als Epos und Rechtsbuch* (Berlin, 1895); id., *Genesis des Mahābhārata* (ib., 1899); E. W. Hopkins, *The Great Epic of India: Its Character and Origin* (New York, 1901); Aiyer, *The Chronology of Ancient India, First Series, Date of the Mahābhārata War* (Madras, 1901); Hermann Jacobi, *Mahabharata* (Bonn, 1903); and Sorensen, *Index to the Mahabharata* (London, 1904–14). For the philosophical ideas of the epic, consult: Garbe, *Die Bhagavatgîtâ* (Leipzig, 1905); Deussen and Strauss, *Vier Philosophische Texte aus dem Mahâbhâratam* (ib., 1906); Bhandarkar, *Vaisnavism, Saivism* (Strassburg, 1913).

MAHADEVA, ma-hä-dā'vȧ. See RUDRA.

MAHADEVI, ma-hä-dā'vē. See DEVI.

MAHAFFY, JOHN PENTLAND (1839–1919). An eminent British classical scholar and historian, born at Chaponnaire, on Lake Geneva, Switzerland. He received his early education in Germany, then entered Trinity College, Dublin, where he graduated in 1859. After 1871 for many years he was professor of ancient history in the University of Dublin. He received honorary degrees from the universities of Dublin, Louvain, St. Andrews, Oxford, and Athens; was made honorary fellow of Queen's College, Oxford, and became senior fellow of Trinity College, Dublin; was decorated with various orders; was elected honorary member of many foreign learned societies; and in 1911 served as president of the Royal Irish Academy. His most important works deal with the history of ancient Greek civilization. Among his publications are the following: *A Translation of Kuno Fischer's Commentary to Kant's Critique* (1866); *Twelve Lectures on Primitive Civilization* (1868); *Prolegomena to Ancient History* (1871); *Social Life in Greece from Homer to Menander* (3d ed., 1877); *Rambles and Studies in Greece* (7th ed., 1913); *A History of Classical Greek Literature* (2d ed., 1892); *The Story of Alexander's Empire* (1886); *The Greek World under Roman Sway* (1890); *The Petrie Papyri Deciphered and Explained*, vols. viii, ix, and xi of the Cunningham Memoirs of the Royal Irish Academy (1891–1905); *Problems in Greek History* (1892); *The Empire of the Ptolemies* (1896); *Progress of Hellenism in Alexander's Empire* (1905); *The Silver Age of the Greek World* (1906); *What Have the Greeks Done for Modern Civilization?* (Lowell Lectures, 1909).

MAHÂ-KÂŚYAPA, mȧ-hä'-käsh'yȧ-pȧ, **KÂŚYAPA**, or **KASSAPA**. Name of one of the 80 great disciples of the Buddha Sakyamuni. He was originally a Brahman, but he became one of the Buddha's first converts. Buddha looked upon him as his successor, and after Buddha's death Kassapa urged the convening of the first general Buddhist council and was instrumental in arranging portions of the canonical works of the Buddhist scriptures. There are numerous legends connected with his life. Consult: Rhys Davids, *Buddhism* (London, 1890); Kern, *Manual of Hindu Buddhism* (Strassburg, 1896); Burnouf, *Introduction à l'histoire du buddhisme indien* (Paris, 1844); id., *Le lotus de la bonne loi* (ib., 1852).

MAHAN, ma-hăn′, ALFRED THAYER (1840–1914). An eminent American naval officer and author. He was born at West Point, N. Y., Sept. 27, 1840, and was the son of Dennis H. Mahan, professor of military engineering at the United States Military Academy and an author of works upon military engineering of wide repute. Alfred T. Mahan graduated from the United States Naval Academy as a midshipman in 1859; was commissioned as a lieutenant (1861), lieutenant commander (1865), commander (1872), captain (1885); was retired at his own request, after 41 years' service, in 1896, and in 1906 was advanced to the rank of rear admiral on the retired list. During the Civil War he served on the South Atlantic blockading squadron, on both Gulf blockading squadrons, and as instructor at the Naval Academy. After the war he commanded the *Aroostook* (1869–71), the *Wasp* (1873–74), the *Wachusett* (1883–85), and the *Chicago* (1893–95).

He took an active part in the establishment of the Naval War College, was ordered to duty in connection with it in 1885, was its president from 1886 to 1889, and was on special duty at the college when retired. In 1898, during the war with Spain, he was called to Washington as a member of the Naval War Board and in 1899 was made a delegate to The Hague Peace Conference. He was a member of the American Historical Association (president, 1902–03) and of the American Academy of Arts and Letters and received the degree of doctor of civil law from Oxford in 1894 and later that of doctor of laws from Cambridge, Harvard, Yale, McGill, and Columbia. He died at Washington, Dec. 1, 1914, of heart disease.

Although his career as a naval officer was highly creditable, Admiral Mahan's reputation rests chiefly upon his historical studies. As a naval historian, his work is of the highest order; as an exponent of naval grand strategy, he is unsurpassed. His first book, a small volume entitled *The Gulf and Inland Waters* (1883), was in no degree extraordinary, though excellent in its way. But in 1890 he published *The Influence of Sea Power upon History, 1660–1783.* This work, one of the greatest historical studies of all time (probably the greatest from a naval point of view), was widely read and at once established Mahan's reputation at home and abroad. Few works have received such instant and wide approval or have exercised so great an effect upon the policy of nations. Later of his writings, almost as powerful, in which his ideas were further developed and extended, include: *The Influence of Sea Power upon the French Revolution and Empire* (1892); *Life of Farragut* (1892); *Life of Nelson, the Embodiment of the Sea Power of Great Britain* (1896); *Interest of America in Sea Power, Present and Future* (1897); *Lessons of the War with Spain* (1899); *The War in South Africa* (1900); *The Problem of Asia* (1900); *Types of Naval Officers Drawn from the History of the British Navy* (1901); *Retrospect and Prospect* (1902), a collection of studies of international relations, naval and political; *Sea Power in its Relation to the War of 1812* (1905); *From Sail to Steam* (1907); *Some Neglected Aspects of War* (1907); *Naval Administration and Warfare* (1908); *The Harvest Within* (1909); *Interest of America in International Conditions* (1910); *Armaments and Arbitration* (1912); *Major Operations of the Navies in the War of American Independence* (1913). He also assisted Sir W. Laird Clowes in the preparation of *The Royal Navy: A History* (1897). At the time of his death Mahan was engaged as research associate in the department of historical research of the Carnegie Institution at Washington and was pursuing a special line of historical investigation with a view to writing a history of American expansion and its bearing upon sea power.

The influence of Admiral Mahan's works has been very great, not only upon naval authorities but upon military men, statesmen, diplomats, and parliaments as well. And it has led the various nations to a more careful consideration of their own naval problems and naval requirements, based upon the lessons of naval history which he was the first to explain fully and to impress effectively upon the world. As a result of his teachings, Germany began a systematic development of her fleet, and Great Britain, realizing as never before her necessity for naval preponderance, initiated a policy from which she has not since deviated. In the United States, except among naval officers, Mahan's influence has been much less than it deserved. By many of the people he was looked upon as a militarist and an opponent of the advocates of peace, chiefly because his historical expositions and conclusions were not carefully studied.

MAHAN, DENNIS HART (1802–71). An American military engineer. He was born in New York, and after graduating at West Point in 1824 was appointed to the engineer corps of the army. In 1825 he was made assistant professor of mathematics at the United States Military Academy, where, in 1832, he became professor of military engineering. He remained at West Point in that capacity till his death—he committed suicide by drowning while temporarily insane. He wrote a number of textbooks on civil and military engineering, which came into general use in schools and colleges in the United States. His *Treatise on Field Fortifications* appeared in 1836 and was supplemented in 1865 by *Military Mining and Siege Operations*, the two constituting parts i and ii respectively of *An Elementary Course of Military Engineering.* He also published *An Elementary Course of Civil Engineering* in 1837, which he rewrote and revised in 1868; *Advanced Guard, Outpost, and Detachment Service of Troops* (1847); *Elementary Treatise on Industrial Drawing* (1853); *Descriptive Geometry* (1864); and an edition of Moseley's *Mechanical Principles of Engineering and Architecture* (1856). A biographical memoir by Gen. H. L. Abbot will be found in volume ii of the *Biographical Memoirs of the National Academy of Sciences* (Washington, 1886).

MAHAN, MILO (1819–70). An American Protestant Episcopal minister, brother of D. H. Mahan, born in Suffolk, Va. He was educated at St. Paul's College, Flushing, Long Island; took orders in 1845; and became rector of Grace Church, Jersey City, in 1848, and assistant minister of St. Mark's, Philadelphia, in 1850. In 1857 he was elected professor of ecclesiastical history in the General Theological Seminary, New York, and in 1864 was called to St. Paul's Church, Baltimore. His published works are: *The Exercise of Faith* (1851); *History of the Church during the First Three Centuries* (1860; new ed., enlarged, 1872); *Reply to Colenso* (1863); *Palmoni: A Free Inquiry* (1864); *Comedy of Canonization* (1868). His works were collected and published, with a memoir, in three volumes, by Hopkins (New York, 1872–75).

MAHANADI, or **MAHANUDDY,** mä'hȧ-nŭd'ĭ (Skt., great river). A river of India, rising in the southern part of the Central Provinces (Map: India, E 5). It flows in an irregular easterly direction across Orissa to the city of Cuttack, where it divides into several arms, forming a large delta, through which it enters the Bay of Bengal about 100 miles southwest of the Ganges Delta. Its entire length is upward of 500 miles, and it is navigable during the rainy season about 300 miles to Sambalpur, but since the opening of the Bengal and Nagpur Railway it has been little used. During this season the volume of water discharged by the Mahanadi is very great, 1,500,000 cubic feet per second through Naraj Gorge as against 1125 cubic feet per second during the dry season; the surplus is being utilized for irrigation by an elaborate system of canals constructed by the British government.

MAHANOY (mä'hȧ-noi') **CITY.** A borough in Schuylkill Co., Pa., 50 miles by rail north by west of Reading, on Mahanoy Creek and on the Philadelphia and Reading and the Lehigh Valley railroads (Map: Pennsylvania, J 5). It is situated in the anthracite region and has extensive coal-mining and shipping interests, besides several shirt factories. The borough is well laid out and has a public-school library and a fine high school. Mahanoy City was settled in 1859 and was chartered as a borough in 1863. Pop., 1900, 13,504; 1910, 15,936; 1920, 15,599.

MAHANUDDY. A river of India. See MAHANADI.

MAHARIF, mä'hȧ-rēf. An antelope of the Sudan (*Hippotragus bakeri*, or *Egoceros equinus bakeri*), allied to the roan and sable antelopes and standing nearly 5 feet high at the withers. It is of a pale liver color, with penciled ears and black stripes across the shoulders. This fine antelope, whose horns are massive, was discovered by Sir Samuel Baker. For the latest account of this animal, consult Theodore Roosevelt, *Life-Histories of African Game Animals* (New York, 1914).

MAHASEER, mä'hȧ-sēr. A large barbel of India and Ceylon (*Barbus tor*), which reaches a length of 6 feet under favorable circumstances. These great fish reside in the streams of the highlands and form one of the principal attractions to the angler in the East. When the rainy season begins, the mahaseers ascend the hill rivers and their tributaries as far as possible and spawn, after which they drop down with the subsiding waters. When the ova hatch, the fry find themselves alone in the scanty headwaters and safe from the devouring appetites of their now absent parents. In these small streams and pools they grow almost unmolested until the next season's high water enables them to go downstream. Thus the continued supply of this and of various other similar fishes is secured to the people of the plains. Mahaseer fishing is one of the leading sports of India.

MAHATMA, mȧ-hăt'mȧ (Skt., possessing a great soul). A name applied in theosophy (q.v.) to a class of saints who are said to refrain from entering Nirvana (q.v.) that they may help mankind by their presence on earth. As a result of their asceticism and meditation, they are supposed to possess superhuman powers, by means of which they are enabled to project their astral bodies to vast distances. The idea of mahatmas is entirely theosophical. Real Oriental philosophy knows nothing of them.

MAHĀVANSA, mä'hȧ-väɴ'sȧ (Pali, great lineage). The title of a celebrated historical work, written in Pali, giving an account in epic form of the island of Lanka, or Ceylon, from the earliest times and the introduction of Buddhism down to the death of King Mahasena, which occurred 302 A.D., and extended later by various additions down to the time of the English occupation. Its authorship is attributed to Mahānāma, who is believed to have composed it between 459 and 477 A.D. Like the Dīpavansa (q.v.), the Mahāvansa is derived from a more ancient source, the historical portion of the *Aṭṭakathā*, which commented on the Buddhist Scriptures after giving an annalistic record by way of introduction. An incomplete edition of the Mahāvansa, with an English translation, was published by G. Turnour (Ceylon, 1837) and reissued later in revised form by L. C. Wijesinha, *Mahāwanso, Translated from the Pāli into English*, vol. i (Colombo, 1889). Consult Geiger, *Dīpavansa und Mahāvansa, die beiden Chroniken der Insel Ceylon* (Erlangen, 1901); the same author's *Die geschichtliche Ueberlieferung in Ceylon* (Leipzig, 1905; Eng. trans., 1908), as well as his edition of the work (London, 1908), which has been translated into English by himself and Bode under the title *The Mahāvaṃsa, the Great Chronicle of Ceylon* (London, 1912). See also the article of Franke, "Dīpavaṃsa und Mahāvaṃsa," in the *Wiener Zeitschrift für die Kunde des Morgenlandes*, vol. xxi (Vienna, 1907).

MAHAVIR, mȧ-hä'vēr', or **MAHAVIRA-CARYA,** mȧ-hä'vēr'ȧ-kär'yȧ (fl. ninth century) (Mahavir the learned). A Hindu mathematician who flourished in the ninth century in what is now the Kingdom of Mysore. He ranks as one of the four or five of the greatest Hindu mathematicians of early times and is one of the two best algebraists. He wrote a work entitled *Ganita-Sāra-Sangraha*, in nine chapters, which was translated into English by Prof. M. Rangācārya and was published by the Madras government in 1912. The work covers the field of elementary algebra and is very rich in Oriental problems.

MAHAVIRA, mä'hȧ-vē'rȧ (Skt. *mahā-vīra*, great hero). Name of the founder of the sect of the Jains. (See JAINISM.) He is known also as *Vardhamāna* 'the Exalted,' *Vīra* 'the Hero,' or as *Jina* 'the Victorious.' He is regarded as the twenty-fourth and last in the long list of deified masters (Tirthakaras) recognized in Jainism, and he appears to have been an elder contemporary of Buddha. His birthplace was at Kotigama (now Vasakund), in northeastern India. His legendary history is given in the *Kalpa-Sūtra* (q.v.) and the *Mahavīra-Charitra*, two works held in great authority by the Jains. According to these works, Mahavira's first birth occurred at a period infinitely remote; it was as a *nayasara*, head man of a village, that he first appeared in the country of Vijaya, subject to Satrumardana. He was next born as Marichi, the grandson of the first Jaina saint Rishabha; he then came to the world of Brahma, was reborn as a worldly-minded Brahman, and after several other births—each separated from the other by an interval passed in one of the Jaina heavens, and each period of life extending to many hundreds of thousands of years—he quitted the state of a deity to obtain immortality as a saint, and was incarnate towards the close of the fourth age, when 75 years and 8½ months of it remained. After he was 30 years of age he renounced worldly pursuits and departed to practice austerities. Finally he became an arhat or jina; and at the age of 72 years, the period of his liberation having arrived, "he resigned his breath," and his body was burned by Indra and other deities, who divided among them such parts as were not destroyed by the flames. The ashes of the pile were distributed among the assistants; the gods erected a splendid monument on the spot, and then returned to their respective heavens.

MAHAYANA, mä′hȧ-yä′nȧ (Skt. *Mahāyāna*, Great Vehicle). The development of Buddhism (q.v.) which within a few centuries after the death of Buddha became the dominant system in northern India as well as in Kashmir and Nepal, and later still spread into China, Korea, Japan, Tibet, Mongolia, etc. Hence it is sometimes spoken of as Northern Buddhism, or the Northern School, as distinct from the Southern School of Ceylon, Siam, and Burma, where the primitive system formulated by Gautama is still the prevailing form. The system of the Northern School is called *Mahāyāna*, "the Great Vehicle or Conveyance," because it is supposed to afford the means of salvation to a much larger number than can find places in the *Hīnayāna*, or "Little Vehicle," as the southern system is disparagingly designated by the followers of the Mahayana School. Mahayana Buddhism emphasizes the intellectual (*prajnā*) side of Buddhist discipline. It denies the existence of an ego, soul, or principle of individuation in both man and the objective universe. This nonego (*anātman*) theory culminates in the conception of *tatvā* or *dharmakāya*, by which term the Mahayana philosophers designate the ultimate conciliation of all contradictions in the absolute. Another doctrine peculiar to Mahanaya Buddhism is that of vicarious sacrifice (*parināmanā*), by means of which one individual may take on himself the *karma* (q.v.) of another. Accordingly the ideal Buddha is not the arhat, who merely seeks his own deliverance from the thrall of karma, but the Bodhisattva, who strives after universal salvation. These tenets have been elaborated in the course of centuries by many philosophers, the most famous being Açvaghosha, Nagarjuna (qq v.), Asanga, and Vasubandhu.

Under the influence of contemporary Hinduism and the Shamanistic notions and practices of the northern barbarians among whom Buddhism had begun to spread animistic beliefs and views concerning the supernatural were introduced, Shivaitic gods and practices were adopted, the attainment of magic powers by means of occult formulas and phrases was eagerly sought, and objects of worship were multiplied. A thousand new Buddhas were invented, among them the Adi-Buddha (q.v.), who came to be worshiped in Nepal as the self-existent Supreme Being. By spontaneous acts of contemplation and wisdom each of these Buddhas projected from his own essence other intelligences, the Bodhisattva, or spiritual sons, who are represented as having reached such a stage of saintship that but one more birth was necessary for them to become Buddhas, but who had decided to forego Buddhahood, and become the guardians of the Buddhist community on earth, and to help mankind, between the death of one earthly Buddha and the appearance of the next. Each of the five earthly Buddhas of the present Kalpa, or age, has his spiritual counterpart, who exists in formless worlds of meditation, as a Dhyani-Buddha (q.v.), and has his reflex Bodhisattva. Three correspond to the three Buddhas who preceded Gautama, one to Maitreya (q.v.), the coming Buddha (expected 2500 years hence), and one, Amitabha, represents the historical Buddha. His spiritual son is Avalokiteshvara, or Padmapani, better known in China as Kwan-yin (q.v.) and in Japan as Kwan-non. It is thus evident that Northern Buddhism has diverged most remarkably from the primitive system evolved by Sakyamuni. In Tibet and Mongolia, where it is known as Lamaism (q.v.), it has become the contrary of Gautama's system, and so far has celibacy been discarded that in certain Japanese sects the priests may marry.

MAHDI, mä′dē (Ar. *al Mahdī*, the Guided One). The name given to the messenger of Allah, who is expected by certain sections of the Mohammedan world to complete the Prophet's work by converting or exterminating the infidels and by equitably dividing the world's goods. It is supposed that he will be a second Mohammed in name and in appearance and, since the time of the Abbasides, that he will carry the black flag of the Prophet. He is to meet Jesus in Damascus and Jerusalem, and to reign seven, eight, or nine years, filling the earth with justice. The idea is not contained in the Koran; but later tradition puts the following words into Mohammed's mouth: "Even though time shall have but one more day to last, God will call up a man of my family who will fill the earth with justice, as it is now filled with iniquity." The Mahdi idea arose in the eastern part of the new Arab empire, nourished by Jewish ideas of the coming of the Messiah and Christian ideas of the second coming of Jesus; more especially in Persia, where the idea of a Saoshyant (q.v.), or Redeemer, was part of the popular tradition of the ruler and the trend to mysticism and deification part of the national character. Its first manifestation was due to the anti-Arab feeling of the Persian Mohammedans who, as legitimists, gathered around Ali, the son-in-law of the Prophet, and resented the neglect of him in favor of the Ommiads, the bitterest opponents of the Prophet. Even during his lifetime Ali was deified, though against his will, by the Jew Abd Allah ibn Saba; and his violent death strengthened the belief that he would be awakened at the end of time and would conquer the world. By others Ali was considered simply to be the *wāsir* or vicar of the Prophet; and in the circles which regarded him as the legitimate Imam (leader) he was confounded sometimes with the Messiah, sometimes with Elijah. The subject became one of fierce dispute between the Shiites and the Sunnites. In the course of time the idea was used as a political weapon by numerous pretenders, and the Mahdi led the Holy War (*jihad*) against Moslems as well as against unbelievers. The first Mahdi was Mohammed ibn al Hanafiyyah, son of Ali, though not of Fatima, who was proclaimed by one Mukhtar in the reign of Abd al Malik (685–705) after the murder of Ali's son Husain. When Mohammed died the Persians refused to believe him dead, but asserted that he would return after 70 years. The idea spread, and since then Mahdis have risen very often among Persians, Egyptians, and the Arabs of the Sudan. One of the most famous of these was the veiled prophet Al Mokanna (see HAKIM IBN ALLAH), the subject of Moore's poem, who came to be regarded as divine and was worshiped for centuries. A large number of Shiites believe that there have existed only 12 Imams. When the twelfth died at Samarra (941), a child of 12 years, it was held that from that time on the Imam would remain concealed, though he may arise as Mahdi at any moment. Of the Egyptian Mahdis, the mad Hakim (996–1021) is most notorious. He also disappeared, but that he will appear again is the firm conviction of the Druses (q.v.) in the Lebanon Mountains and the Hauran. Of the sects that have sprung from this idea, the Ismailis may be mentioned, who expect the return of a Mahdi, Mohammed ibn Ismail of the family of Ali. The Karmathians also took their origin from this idea. (See MOHAMMEDAN SECTS.) Even orthodox Islam has been affected, and had its Mahdi in the person of Ibn Tumart (1121), the founder of the Almohade Berber power. See ALMOHADES.

The modern Mahdi is a product of one of the many religious orders (the Sammaniyyah) which, as a protest against the encroachment of the Christian civilization, honeycomb the Moslem world and are especially numerous in northern Africa. Born in 1844 or 1848 in the Province of Dongola, he took the name Mohammed Ahmed, asserting that his father was descended from Husain and his mother from Abbas. He studied at Kereri, 4 miles north of Omdurman, at Khartum, and in Berber. In 1870 he allied himself with the Sammani Order, passing part of his time with his uncle, a shipbuilder on the island of Aba in the White Nile, where he lived an ascetic life. He then entered a minor order at Musalemia on the Blue Nile. In these circles the year 1882 (1300 A.H.) was supposed to be the Mahdi year. Mohammed soon became famous in the country between the White and the Blue Niles. He was joined in Kordofan by a Bakkara Bedouin named Abd Allah, who afterward became his Caliph. He was proclaimed Mahdi in El Obeid in 1880, but returned to Aba to continue his ascetic life. In May, 1881, he came forward openly and sent circulars to the chiefs of Islam preaching the Jihad, or Holy War, the conversion of all unbelievers, a return to the simple faith of the Prophet, simplicity in dress and manners, and a sort of social communism and asceticism. Afraid of the Egyptian government, he collected a band of Dijem and Kinaru Bedouins and proclaimed the Jihad. In July, 1881, a small expedition sent against him was destroyed on the island. Imitating the Prophet, he left Aba, his Mecca, and came to Masa in southern Kordofan, which he proclaimed his Medina. For his subsequent movements, see SUDAN. He died of smallpox. Consult: Darmesteter, *The Mahdi* (New York, 1885); Snouck Hurgronje, in *Revue Coloniale Internationale* (1886); G. Hoffmann, *Mahdithum* (Kiel, 1899); Ernst Müller, *Beiträge zur Mahdilehre des Islams* (Heidelberg, 1901); D. B. MacDonald, *Aspects of Islam* (New York, 1911).

MAHÉ, mȧ'hȧ'. The principal island of the Seychelles (q.v.).

MAHÉ. A French town and colony in India, at the mouth of the Mahé River on the west coast, 5 miles south of Tellicherri (Map: India, C 7). It was settled in 1722 and was taken by the English in 1761 and again in 1779; it was finally restored to France in 1815. Area of colony, 25 square miles; pop., 1912, 10,431.

MAHICAN, mȧ-hē'kȧn (Amer. Indian, wolf). An important Algonquian tribe or confederacy formerly occupying most of the Hudson River valley and extending eastward into Massachusetts. They were closely connected with the Delaware and Munsee on the south and with the Mohegan and Wappinger on the east, all of these being known collectively to the French as *Loup*, or Wolf, Indians. When first known their council fire was at Schodac, on an island near Albany, and their territory contained some 40 villages. In consequence of the inroads of the Iroquois they removed their capital in 1664 to Westenhuck, the modern Stockbridge, Mass. By successive sales and removals, as the white settlements pressed upon them, they lost their territory and tribal identity, most of them becoming merged with the Delaware. In 1736 those remaining in western Massachusetts were gathered into a mission at Stockbridge and became known as the Stockbridge Indians. They are the only Mahican who have preserved their identity. A few others remained about their ancient homes on the Hudson for some years after the Revolution, but finally disappeared unnoticed. Those of Stockbridge removed later to the Iroquois country in New York, and are now settled, together with a part of the Munsee, upon a reservation near Green Bay, Wis., all completely civilized.

MAHI KANTHA, mȧ-hē' kän'tȧ (Banks of the Mahi). A group of native states in the northeastern part of Gujarat, India, forming a political agency under the government of the Bombay Presidency. It is bounded on the northeast by the Rajputana states of Udiapur and Dungarpur, on the southeast by Rewa Kantha, on the south by the British District of Kaira, and on the west by Baroda, Palanpur, and the British District of Ahmadabad. The area is 3125 square miles, of which the State of Idar, by far the most important of the group, occupies 1669 square miles. Eleven states besides Idar are of some importance; the remainder are estates belonging to Rajput or Koli thakurs (noblemen), once lawless feudatories of Baroda. The climate is fairly good; the hottest months are April and May and the coolest month January. The average annual rainfall at Idar is 34 inches. Of the total area about 27 per cent is cultivable. Three railways traverse the agency. The country is subject to native chiefs who are under the supervision of the British political agent. The population has been as follows: in 1872, 447,056; in 1881, 517,485; in 1891, 581,568; in 1901, 361,545 (the loss per cent being 37.8); in 1911, 412,631 (increase per cent 14.1). The large decrease in 1891–1901 was principally due to famine, especially in 1899–1900. In 1901, about 90 per cent of the inhabitants were Hindu, 5 per cent Mohammedan, and 3 per cent Jain; of the Hindus, about 92,000 were Kolis (laborers), 68,000 Kunbis (cultivators), 27,000 Brahmans. The aboriginal tribes are chiefly Bhils, who are animists, though many have been censused as Hindus; in 1901, they numbered about 18,000. The Bhils are a remarkable people, hardy and enterprising, but superstitious and often thievish. Of the total population in 1901, 12 per cent of the males and 0.3 per cent of the females were recorded as literate. Mahi Kantha contains six towns and 1723 villages. The towns are Idar, Amadnagar, Mansa, Vadali, Pethapur, and Sadra.

MAHIM, mȧ-hēm′. A town and railway station of the island of Bombay, nine miles north of the city of Bombay, situated on the south side of the channel separating the island from Salsette at the point where they are connected by a causeway. The passage is commanded by a fort. The town is inhabited chiefly by Christians of Portuguese descent, who have a church and other relics of former prosperity. The only orphanage in the province, a Scottish institution founded in 1859, is located here. The inhabitants are chiefly employed in fishing, the place being famous for its oysters. The bund was erected largely at the expense of Parsi benefactors. Pop., 1911, 6,643.

MAHINDA, mȧ-hēn′dȧ. The apostle who introduced Buddhism into Ceylon in the third century B.C. He is said to have been a son of Asoka (q.v.), and his birthplace was the town of Mahinda Vessanagara (now Besnagar) in the Province of Ujjain, western India, of which his father was Viceroy at the time. He was said to be 32 years of age when he set out on his mission to Ceylon, accompanied by other Buddhist missionaries; and it was his sister who is supposed to have brought the branch of the sacred bo tree (q.v.) to Ceylon. His death (193 B.C.) occurred at a place not far from Anuradhapura, at the age of 60. Consult C. M. Duff, *The Chronology of India* (London, 1899).

MAHLER, mä′lẽr, Gustav (1860–1911). An Austrian musical conductor and composer, born at Kalischt, Bohemia. He studied at the Iglau Gymnasium and in 1877 went to Vienna, where he became a student at the university and at the conservatory. After graduation he acted as conductor of various theatres at Cassel (1883–85); at Prague, as Anton Seidl's successor (1885–86); at Leipzig (1886–88); at the Royal Opera, Budapest (1881–91); at Hamburg (1891–97); and in the latter year became director of the Court opera at Vienna, which post he filled with distinction till 1907. During the season of 1907–08 he was conductor of the German operas at the Metropolitan Opera House, New York. Elected conductor of the New York Philharmonic Society in 1909, he reorganized this orchestra completely and brought it to a high level of excellence. He died in Vienna. He was one of the greatest masters of the baton, a man of indomitable energy and magnetic personality. As a composer, he failed signally because of lack of individuality, inventive power, concentration, and moderation. Yet his ambition was boundless. All his works are planned on the grandest scale, calling for an enormous technical apparatus, which he handles, indeed, with absolute mastery. The first performance of his *Eighth Symphony* at Munich (Sept. 12, 1910) was made the occasion of a special festival. The work lasted one hour and three-quarters, and Mahler conducted an orchestra of 170 players, a mixed chorus of 500 voices, and a children's chorus of 350 voices, assisted by organ and piano. He wrote nine symphonies (most of which demand the coöperation of a large chorus); two operas, *Die Argonauten, Rübezahl;* two song cycles with orchestra, *Kinder-Totenlieder* and *Das Lied von der Erde;* chamber music and songs. An unfinished tenth symphony was completed from the composer's sketches by Franz Mikorey (1913). Consult Paul Stefan, *Gustav Mahler: Eine Studie über Persönlichkeit und Werk* (Munich, 1912; Eng. trans. by T. E. Clark, New York, 1913), and Richard Specht, *Gustav Mahler* (Berlin, 1913).

MAHLMANN, mäl′mȧn, Siegfried August (1771–1826). A German poet, born and educated at Leipzig. He traveled as tutor until 1798; became editor of the *Zeitung für die elegante Welt* (1805) and of the *Leipziger Zeitung* (1810–17); wrote clever burlesques, including *Herodes vor Bethlehem* (1803), a satire on Kotzebue's (q.v.) *Hussiten vor Naumburg,* and *Marionettentheater* (1806). His best known productions are his lyrics, of which some are still popular in Germany, as e.g., *Mein Lebenslauf ist Lieb und Lust.* Mahlmann's *Erzählungen und Märchen* were published in 1802, and his collected works in 1839–40.

MAHLSTICK, mäl′stĭk (Ger. *Mahlstock, Malstock,* painting stick, from *malen,* to paint + *Stock,* stick), or Rest Stick. A round staff, from 3 to 4 feet long, tapering towards one end, which terminates in a small ball, sometimes covered with buckskin to prevent injury to the picture against which it rests. The mahlstick is held in the painter's left hand, to support the right hand, with which he holds his brush when painting. It was formerly more generally used than at present, as it is now thought to restrict the freedom of touch in painting.

MÄHLY, mā′lê, Jakob (1828–1902). A Swiss classical scholar and poet, born at Basel. He studied at Basel and Göttingen, and afterward became docent and professor of classical philology at the university of his native town. His works include: *Sebastian Castellio* (1862); *Angelus Politianus* (1864); *Geschichte der antiken Litteratur* (1880); *Richard Bentley* (1868); the epic poem *Mathilde* (1854); and excellent translations of Euripides, Æschylus, and Plutarch.

MAHMUD, mȧ-mo͞od′. The name of two sultans of Turkey.—Mahmud I (1696–1754) was Sultan from 1730 to 1754. His reign was of no especial importance.—Mahmud II (1785–1839) was Sultan from 1808 to 1839. He was a younger son of Abd-ul-Hamid I, and on the deposition of his brother, Mustapha IV, by Bairaktar, Pasha of Rustchuk, was raised to the throne, Aug. 1, 1808. Bairaktar became his Grand Vizier and aided him in his attempts to reform the organization of the Turkish army. The Janizaries, emboldened by their successful opposition to the same attempt on the part of Selim III, rose in rebellion, and the murder of the Vizier put a stop for the time being to the carrying out of any military reforms. Mahmud was also attacked by the rebels, but he secured his life and throne by the death of Mustapha, thus making himself the sole representative of the house of Osman, upon the continuance of which its followers believe the Empire to depend. The Ottoman Empire was in a critical condition, threatened by Russia and by rebellious vassals within its own borders. After a conflict which completely prostrated the strength of Turkey peace was concluded with Russia in 1812 at Bucharest, the Russian frontier being advanced to the river Pruth, but most of Wallachia and all of Moldavia were restored to Turkey. Mahmud now applied himself to the promotion of radical reforms in all departments of the government. Ali Pasha, the rebellious Pasha of Janina, was overthrown and killed in 1822. Greece revolted in 1821, and its independence was secured by the battle of Navarino in 1827, but it was not recognized as a separate kingdom by Turkey till April, 1830. During the progress of the Greek Revolution Mahmud had been steadily though secretly maturing his plans of military reform, and in June, 1826, the success of his schemes was crowned by the destruction of the Janizaries (q.v.), after which the army was reorganized on the European model and military schools were established. The consequent confusion into which Turkey was thrown was immediately taken advantage of by Russia for obtaining fresh concessions. Mahmud, however, despite these interruptions, proceeded in those plans of reform which he judged essential to the stability of the Empire; and the disastrous termination of the war with Russia (1828–29) (see ADRIANOPLE), far from interfering with his projects, only stimulated him to renewed exertion. Meanwhile the frequent unsuccessful wars, together with the disaffection manifested by the Christian population of Turkey, aroused in the mind of Mehemet Ali, Pasha of Egypt, the hope of achieving his independence. (See MEHEMET ALI.) The Egyptian army, under Ibrahim Pasha, overran Syria in 1831–32 and advanced through Asia Minor, winning a great victory at Konieh. The intervention of Russia compelled both parties to agree to a treaty (1833) which was satisfactory to neither. Mahmud, however, was forced to grant fresh concessions to the Czar, in return for the Russian aid, by the Treaty of Unkiar-Skelessi, July 8, 1833. He again pursued with undiminished vigor his reforms in the administration, the principal improvements being the modification and readjustment of the more oppressive taxes and the granting of increased privileges to foreign merchants. In 1839 he renewed the war with Mehemet Ali, but died on July 1, before he had heard of the decisive defeat of his army at Nizib, June 24. See TURKEY; MEHEMET ALI.

MAHMUD OF GHAZNI, gäz′nē. A Mohammedan ruler and conqueror. See GHAZNIVIDES.

MAHOG′ANY (from South Amer. *mahogoni*, the native name). The timber of a number of trees, the most highly esteemed being that of *Swietenia mahagoni*, a large tree of the family Meliaceæ, native of tropical America. The tree attains a height of 60 to 100 feet and a diameter of 6 feet or more, but these dimensions are not common. The former supplies of Cuba, Jamaica, and other islands of the West Indies are greatly reduced, and Central America meets the commercial demand. As occasional specimens the tree is met with in the extreme south of Florida, but not of a size or abundance to be of much economic value. The tree has compound leaves with usually four, sometimes three or five, pairs of leaflets, and panicles of small white or yellowish flowers that sometimes turn reddish. The wood is rich reddish brown, varying widely in its shades and markings and capable of receiving a high polish. The tree varies greatly in its rate of growth, being most rapid upon rich moist soils, but here the timber is frequently of coarser grain than when grown more slowly upon less fertile soils. The character of the timber produced in different countries varies. That from Santo Domingo (also known as Spanish mahogany) and Cuba is considered the best, and that from Honduras not so valuable, because it is less finely grained and marked. The cutting and removing of this timber to the coast for export give employment to a large number of men and oxen. The logs as exported are usually squared so as to get rid of as much of the less valuable sapwood as possible, and also to admit of better conveyance. Formerly mahogany was largely used in shipbuilding, especially in the Spanish navy, but it is now almost entirely a cabinetmaker's wood, entering into manifold uses either solid or as a veneer. Mahogany was introduced into England by Sir Walter Raleigh in 1597, it having been used in the repair of one of his ships; but while the wood was greatly admired, it did not become an article of commerce until about 150 years later. Two other little-known species, *Swietenia angolensis* and *Swietenia humilis*, occur in Central America. White mahogany, or Prima Vera, *Tabebuia donnellsmithii*, is a Mexican tree belonging to the family Bignoniaceæ. It attains a height of 50 to 75 feet and a diameter of 4 feet. The timber is imported and used for furniture to some extent. The term is also used in trade to include other woods. In India, *Cedrela toona*, a valuable tree of the same family as *Swietenia*, is called mahogany. Its timber is quite like the true mahogany. In Australia the name mahogany is applied to the timber of a number of species of *Eucalyptus* (q.v.). In the western United States *Cercocarpus ledifolius* is called mountain mahogany and *Cercocarpus parvifolius* valley mahogany. There are also several varieties of the latter. These trees belong to the family Rosaceæ, and are found from Colorado to New Mexico and westward to California. The East Indian mahogany is the timber of the rohuna tree (*Soymida febrifuga*), and the African mahogany that of *Khaya senegalensis*, both belonging to the same natural order as the true mahogany. *Chlorophora excelsa* furnishes some of the African mahogany; *Hovenia dulcis*, the Japanese mahogany; and *Triplochiton utile*, the Gold Coast mahogany.

MAHOGANY CEMENT. See CEMENT.

MAHOMET. See MOHAMMED.

MAHOMET'S (mȧ-hŏm′ĕts) **COFFIN.** According to an old legend, the Prophet's coffin in the tomb at Medina was suspended in the air, upheld, according to the faithful, by four angels who are relieved hourly. Another version of the fable describes the coffin as made of iron and held in the air by powerful magnets.

MAHÓN, mȧ-hōn′. The chief town of the island of Minorca. See Port Mahón.

MAHON, Charles. See Stanhope, Charles Mahon, third Earl.

MAHONE, mȧ-hōn′, William (1826–95). An American soldier and legislator. He was born in Southampton Co., Va., graduated at the Virginia Military Institute in 1847, and became a civil engineer. On the outbreak of the Civil War he joined the Confederate army and assisted in the capture of the Norfolk Navy Yard; participated in most of the battles of the Peninsular and Rappahannock campaigns; was distinguished for bravery at Petersburg, where he earned the title "The Hero of the Crater"; became a major general and commanded a division. After the war he became president of the Norfolk and Tennessee Railroad, took a prominent part in Reconstruction politics, and was effective in securing the nomination of Gilbert C. Walker in 1870, a compromise candidate for Governor of Virginia, whereby the conservatives regained control of the State. He was an unsuccessful candidate for the Democratic nomination to the governorship of Virginia in 1878, became the recognized leader of the "Readjusters," a Democratic faction which favored a partial or conditional repudiation of the State debt (see Readjusters), and in 1880 was elected largely by this faction to the United States Senate. He here took the unexpected course of allying himself with the Republicans, and thus brought about a tie in place of the slight Democratic majority which had been expected. He further alienated his constituents by his use of the Federal patronage in Virginia which had been assigned to him by President Arthur, and at the expiration of his term in 1887 he failed to secure a reëlection.

MAHO′NIA. A genus of shrubs closely related to the barberry (q.v.).

MAHO′NY, Francis Sylvester (1804–66), best known by his pseudonym of Father Prout. An Irish poet and humorist. He was born in Cork. His father wished him to prepare for the bar, but he chose the Church, and, after studying at the Jesuit colleges of Clongoweswood, County Kildare, Ireland, and St. Acheul, Amiens, and at Rome, was admitted to the Society of Jesus. He was appointed prefect of studies and afterward master of rhetoric in the Jesuit college at Clongoweswood, Ireland, but, becoming involved in a misadventure, was obliged to resign his position, and, returning to Italy, was dropped from his order. The priesthood, indeed, was not congenial to him, and clerical labors soon gave place to a literary life in London. He began in 1834 to contribute to *Fraser's Magazine* a series of papers which were afterward collected and published in book form as *The Reliques of Father Prout*. They comprised sketches in prose and verse ("The Bells of Shandon" being the best known), parodies, playful translations into Greek, Latin, and French, or from other languages. He contributed to *Bentley's Miscellany* and furnished an inaugural ode to the first number of the *Cornhill Magazine*. He was the first Rome correspondent of the London *Daily News*, and was Paris correspondent of the London *Globe* for several years after 1858. The last two years of his life were passed in a monastery. The *Reliques of Father Prout* was included in Bohn's Illustrated Library in 1860. Another volume, *Final Reliques*, was edited by Douglas Jerrold and published in 1876. *The Works of Father Prout*, edited by Charles Kent, were published in 1881. *Facts and Figures from Italy* (1847) was made from his Rome letters to the London *Daily News*. He died in Paris.

MAHOWA. See Butter Tree.

MAHRA, mä′rȧ, **MAHRI**, or Ehkili. A tribe of Hadramaut in southern Arabia. They are of interest as representing, according to several authorities, the ancient Himyarites. This gives them an importance outside their numbers and their primitive (or perhaps degenerate) culture. Their language seems related to that of the Himyarites. Consult: Van den Berg, *Hadramout* (Paris, 1886; Eng. trans., London, 1887); Hirsch, *Reisen in Süd-Arabien, Mahra-Land und Hadramut* (Leipzig, 1897); Bent, *Southern Arabia* (London, 1900).

MAHRATTAS, mȧ-rȧt′tȧz. A landed people inhabiting Central India, south of the Ganges from Gwalior to Goa. They are a mixed people, speaking a Hindu language, the Marathi (q.v.), and are Hindus in religion. There is no sharp line of demarcation between the Mahrattas and the Kunbis, or peasant cultivators, who worship the same local divinities without being Hindus in the proper sense of the term. The Mahrattas (Marathas) are a vigorous and active race, possessed of great endurance, and distinguished for military courage, with which cruelty has been combined. Their origin is obscure. They seem to have entered India prior to the Mohammedan conquests by Mahmud of Ghazni at the beginning of the eleventh century. The founder of the Mahratta power was Sivaji Bhonsla (1627–80), a freebooter or adventurer, whose father was an officer in the service of the last King of Bijapur. By policy or by force he eventually succeeded in compelling the several independent chiefs to acknowledge him as their leader, and with the large army then at his command he overran and subdued a large portion of the Emperor of Delhi's territory. In 1674 Sivaji was formally proclaimed Maharajah of the Konkan. He organized and levied a species of blackmail on his neighbors, called *chauth* (Skt. *caturtha*, "four"), a fourth of the land revenues. Sivaji's son, Sambaji, succeeded him in 1680, and after vigorously following out his father's policy was taken prisoner by Aurungzebe (q.v.) in 1689 and put to death. The incapacity of the subsequent rulers gave free rein to the intrigues and ambitions of their Brahman prime ministers or *peshwas*. (See Peshwa.) Soon the Peshwa became the hereditary sovereign, Sivaji's descendant being degraded to the position of a titular monarch. In this respect Mahratta history is of special interest as presenting a struggle between the priestly and warrior castes, with the victory finally won by the Brahmans. Early in the eighteenth century five Mahratta states were formed—Baroda, Gwalior, Indore, Nagpur, and the Peshwa's dominions (the capital of which was Poona). The usual internecine wars followed, and ultimately the East India Company was compelled to interfere. The invasion of the Empire of Delhi by the Persian Nadir Shah in 1739 afforded the Peshwas an opportunity of which they eagerly availed themselves, to wrest additional territory from the Mogul Emperor. From this time they discharged the office of arbiters in the quarrels between the Emperor, his Vizier, and his rebellious subjects; but the defeat they sustained in January, 1761, at the hands of Ahmed Shah, the ruler of Afghanistan, on the field of Panipat, greatly weakened their power for a time. Although there was some fighting as early as 1775, the real wars between the British and the Mahrattas began in 1779 during the administration of Warren Hastings. The third Mahratta war of 1803–05 was marked by the brilliant victories of Wellesley, Lake, and others over the armies of Gwalior, Indore, and Nagpur, and resulted in large acquisitions of territory by the British. In 1817 the Peshwa of the Mahrattas took up arms against the British, who were also attacked by the Rajah of Nagpur and by the ruler of Indore. The British speedily broke the power of the enemy and annexed the Peshwa's dominions to the Presidency of Bombay. Indore became a vassal state of the British, who at a later period annexed Nagpur. The Mahratta State of Gwalior, which had risen to great power in the eighteenth century, came under British control in 1843–44. The three Mahratta states of Indore, Gwalior, and Baroda refrained from participation in the Sepoy Mutiny of 1857. The ruler of Indore bears the name of Holkar (q.v.), that of Gwalior is called Sindia (q.v.), and that of Baroda is known as the Gaikwar (q.v.). Consult: Broughton, *Letters Written in a Mahratta Camp* (London, 1813; new ed., Westminster, 1892); Grant-Duff, *History of the Mahrattas* (Bombay, 1863); Forrest, *Selections from the State Papers in the Bombay Secretariat: Maratha Series* (ib., 1885); *Gazetteer of the Bombay Presidency*, vol. i (ib., 1896); Ranade, *Rise of the Maratha Power* (ib., 1900); and the index to the *Imperial Gazetteer of India* (Oxford, 1909).

MÄHREN, mâ′ren. See MORAVIA.

MÄHRISCH-OSTRAU, mâ′rĭsh ŏ′strou. A frontier town in the Crownland of Moravia, Austria, on the Ostrawitza, 60 miles west-southwest of Cracow (Map: Austria-Hungary, F 2). Its varied manufactures include iron, malt, tin, zinc, bricks, paraffin, ether, roofing paper, metal ware, malt, brandy, soap, petroleum, and rum. In the vicinity are the large Rothschild Iron Works of Witkowitz. The coal mining and the coke industry are also important and employ more than 25,000 men (in the community). Among its institutions is a school of mines. Pop., 1900, 30,125; 1910, 36,754.

MÄHRISCH-SCHÖNBERG. See SCHÖNBERG.

MAHWA, mä′wȧ. A tropical tree. See BUTTER TREE.

MAHY, THOMAS DE, MARQUIS DE FAVRAS. See FAVRAS, THOMAS DE MAHY.

MAI, mī, ANGELO, CARDINAL (1782–1854). A distinguished Italian antiquary and philologist. He was born in the village of Schilpario in Lombardy. He was educated and lived till 1808 in establishments belonging to the Jesuits, but obtained an appointment, first as associate and ultimately as custodian of the celebrated Ambrosian Library at Milan. In 1813 he published a translation of Isocrates, *De Permutatione*, with a commentary; but his reputation is due much more to his publications of the palimpsests or rewritten manuscripts, the first specimens of which he issued at Milan. (See PALIMPSEST.) His earliest publications in that line dealt with fragments of *Cicero's Orations* (*Pro Scauro, Pro Tullio, Pro Flacco, etc.*); of the *Vidularia*, a lost play of Plautus; of *Letters of Fronto* (q.v.), Marcus Aurelius' preceptor (later, he found many more letters of Fronto in the Vatican Library; see below); the *Chronicon* of Eusebius; nine books of the *Antiquitates* of Dionysius Halicarnassus, and other less important works, which, however, were entirely eclipsed by his well-known edition and restoration of the *De Republica* of Cicero, published in 1820. Meanwhile Mai had been invited to Rome by Pius VII and had been named chief keeper of the Vatican Library (1819). He at once turned his attention to the unedited manuscripts of the Vatican and, after a short examination of this noble collection, undertook, as the mission of his life, the task of publishing those among them which had been overlooked by earlier editors. This task he steadily pursued; and although he was appointed in 1833 to the onerous office of Secretary of the Propaganda and, in 1838, to the cardinalate itself, his Roman publications form a collection of an extent and importance almost unexampled in modern times. His first series of these publications was in 10 quarto volumes, entitled *Scriptorum Veterum Nova Collectio, e Vaticanis Codicibus Edita* (Rome, 1825–38). It consists, like the great collections of Mabillon, Montfaucon, D'Achery, and others, of miscellaneous unpublished works, partly sacred, partly profane, and indifferently in the Greek and the Latin languages, comprising an entire volume of palimpsest fragments of the Greek historians Polybius, Diodorus, Dion, Dionysius, and others. The succeeding collections—viz., *Classici Scriptores e Codicibus Vaticanis Editi* (10 vols., 8vo, 1828–38), *Spicilegium Romanum* (10 vols., 8vo, 1839–44), and *Patrum Nova Bibliotheca* (6 vols., 4to, 1852–54)—are all on the same plan, and all equally replete with new and interesting materials. Consult: Prina, *Biografia del cardinale Angelo Mai* (Bergamo, 1882); G. Poletto, *Del cardinale Angelo Mai e de' servi, studi, e scoperte* (Siena, 1889); J. E. Sandys, *A History of Classical Scholarship*, vols. i, iii (Cambridge, 1908).

MAIA, mā′yȧ (Lat., from Gk. *Maĩa*). 1. In Greek mythology, one of the Pleiades; the eldest daughter of Atlas by Pleione, a daughter of Oceanus. She became the mother of Hermes by Zeus. (Consult the so-called *Homeric Hymn to Mercury*, trans. by Shelley.) On account of the similarity of name she was identified by the Romans with Maia Majesta, an ancient Italian goddess of spring, who was also called Bona Dea, Ops, and Fauna. In this aspect she was regarded as Vulcan's wife, and a pregnant sow was sacrificed to her on the first of May. Consult W. W. Fowler, *Roman Festivals* (London, 1899), and Georg Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912). 2. The name Maia is also given to the star 20 Pleiadum.

MAIDEN, THE. A name given to a machine in Edinburgh, Scotland, for beheading criminals. It was made in 1564 by order of the provost and magistrates, and the first recorded execution with it was that of Thomas Scott, one of the murderers of Rizzio, on April 3, 1565. In June, 1581, it was used in the execution of the Earl of Morton, by whom Hume of Godscroft alleges that it was invented. Its use was continued until 1710, when decapitation of criminals in Scotland was abolished. It was subsequently preserved in the Museum of the Antiquaries of

Scotland. It was first called indifferently "the maiden" and "the widow." A frightful instrument of punishment used in Germany in the Middle Ages was called "the virgin." But it had no resemblance to the maiden, which was similar to the French guillotine (q.v.), although it had no turning plank on which to bind the criminal. Consult W. T. McCulloch, "History of the 'Maiden' or Scottish Beheading Machine, with Notices of the Criminals who Suffered by it," in the *Proceedings* of the Society of Antiquaries of Scotland.

MAIDEN ASSIZE. A session of the English Court of Assize at which the justice takes his seat of office and immediately adjourns without hearing any trials. It is customary for the sheriff of the county to present the judge with a pair of white gloves as a symbol of the innocent character of his administration. See ASSIZE.

MAID'ENHAIR (*maiden* + *hair*, so called from the shape of the stalks), *Adiantum capillus veneris.* A small, delicate, and graceful fern, with bipinnate fronds, alternate obovate and wedge-shaped membranaceous pinnules on capillary stalks. It grows on moist rocks and old walls, especially near the sea in the south of Europe, where it covers the insides of wells and the basins of fountains with a tapestry of the most delicate green. It is also found in many places in the United States. Another species of the same genus, *Adiantum pedatum*, a native of North America and eastern Asia, with pedate leaves, has a sweet, fragrant rootstock, from which capillaire is made. One of the most popular ferns in house culture is the *Adiantum farleyense.* The name is also sometimes given to species of spleenwort (*Asplenium*), one of which is shown on the Colored Plate of FERNS.

MAIDENHAIR TREE, *Ginkgo biloba.* See GINKGO; GYMNOSPERMS.

MAIDENHEAD, mā'd'n-hĕd. A market town in Berkshire, England, situated amid beautiful scenery, on the Thames, 24 miles west of London. It carries on some trade in meal, malt, and timber. It was formerly known as Maidenhythe. Its charter was granted by Henry VI, and in 1578 it was made a free borough. It owns Kidwells Park and a large recreation ground and maintains a bathing establishment, isolation hospital, and sewage farm. Maidenhead, though an ancient town, is now practically a residential suburb for wealthy Londoners and a favorite starting place for boating parties on the Thames. Pop., 1901, 13,000; 1911, 15,219.

MAIDEN QUEEN. A title given to Queen Elizabeth of England.

MAID MARIAN. A maiden presumably of French origin, the traditional female companion of Robin Hood, the legendary English outlaw. Later she is represented as one of the characters in the famous Morris dance (q.v.), which formed one of the essential features in all the principal village festivities during the reign of Henry VIII of England. Maid Marian was personated originally by a boy in girl's clothing and was called queen of the May, as this dance was one of the sports of May Day, Holy Thursday, weddings, etc. In fiction *Maid Marian* has been made the heroine of successful stories, notably *Maid Marian* by T. L. Peacock. See HOOD, ROBIN.

MAID'MENT, JAMES (?1795–1879). A Scottish antiquary, born in London. He was called to the Scottish bar in 1817 and soon gained reputation as an advocate in peerage cases and in general practice. In consequence of his interest in antiquarian researches he became known to Scott, and an intimate friendship followed. He died at Edinburgh, Oct. 24, 1879. Among his many publications are: *Reliquæ Scoticæ* (1828); *Analecta Scotica* (1834–37); *Bannatyniana: Notices Relative to the Bannatyne Club* (1836); *Edinburgh Portraits* (1837); *Scottish Elegiac Verses* (1842); *Scottish Ballads and Songs* (1859); *A Book of Scottish Pasquils* (1868); and, with W. H. Logan, the valuable work, *Dramatists of the Restoration* (14 vols., 1877). Maidment also gathered a library of rare books, the sale of which took 15 days (1880). Consult: T. G. Stevenson, *Bibliography of Maidment* (Edinburgh, 1883); J. Irving, *Book of Scotsmen Eminent for Achievement* (London, 1882); J. C. Hadden, in *Dictionary of National Biography*, vol. xxxv (ib., 1893).

MAID OF ARTOIS, är'twä', THE. An opera by Balfe (1836) with libretto by Alfred Bunn. It introduces the song "The Light of Other Days," said to have been the most popular song of its time in England.

MAID OF ATHENS. A well-known poem by Lord Byron, written in Athens and said to have been inspired by Theresa Macri, the daughter of the English vice consul.

MAID OF BATH, THE. 1. A title given to Miss Linley, afterward the wife of Richard Brinsley Sheridan. 2. A farce by Foote (1771), in which, in the character of Flint, he pilloried Walter Long for his treatment of Miss Linley.

MAID OF HONOR. See HOUSEHOLD, ROYAL.

MAID OF KENT. A name frequently given to Elizabeth Barton (q.v.).

MAID OF ORLÉANS, ôr'lâ'äɴ'. See JOAN OF ARC.

MAID OF THE MIST. 1. A name given to the heroine in Scott's *Anne of Geierstein.* 2. A small steamboat once used on the Niagara River, between the Falls and the Whirlpool Rapids, to carry visitors close to the cataract. In 1867, in order to avoid seizure by the sheriff, she made the dangerous trip through the Rapids with only slight injury.

MAID'STONE. The county town of Kent, England, and a municipal borough, on the Medway, 34 miles east-southeast of London (Map: England, G 5). It is built on the slopes of a picturesque valley on the east bank of the river, which is spanned by a handsome bridge. The principal buildings of interest are the ancient collegiate church of All Saints, the college of All Saints, both dating from the fourteenth century, and the sixteenth-century manor house, in which the finest provincial museum in England is located. The archbishops of Canterbury maintained a palace here until the Reformation, the building now being used to house the school of science and art. The municipality maintains free libraries, parks and recreation grounds, public baths, a corn exchange, concert hall, and hospital. Sewage is chemically treated for fertilizing purposes, and there is a refuse destructor in conjunction with an electric-lighting plant. Maidstone is the centre of a large agricultural and hop-growing district, and its industries include breweries, oil mills, and paper mills, rope, cement, lime, and brick works. It was the Saxon Medwegestun. It witnessed the defeat of the Kentish Royalists by Fairfax in 1648. Pop., 1901, 33,500; 1911, 35,475. Consult: Gilbert, *History of the Collegiate Church of All Saints* (Maidstone, 1866); Russell, *History of Maidstone* (London, 1882; new ed., 1885); Cave-Browne, *Maidstone* (ib., 1889).

MAID'S TRAGEDY. A play by Beaumont and Fletcher, written not later than 1611 and printed in 1619. The fourth and fifth acts are mainly by Fletcher.

MAIDU, mī′dōō (the people). A group of small tribes, formerly living along the eastern affluents of the Upper Sacramento River in northern California. They went nearly naked, lived chiefly upon acorns and piñons, and built a species of hogân or dugout of boards, with wicker granaries for storing acorns, and large round town houses for public ceremonials. They had a number of dances, the chief of which was the acorn dance, and a peculiar secret society for boys. They constituted a distinct linguistic stock known as the Pujunan. They are now gathered upon the Round Valley Reservation to the number of 1100. They are basket makers, but fashion simpler designs than the neighboring Pomo tribes. Consult: R. B. Dixon, "Maidu Myths" and "The Northern Maidu," in *American Museum of Natural History, Bulletin*, vol. xvii (New York, 1902–05); id., "Maidu," in Franz Boas, *Handbook of American Indians*, part i (Washington, 1911); id., "Maidu Texts," in *American Ethnological Society, Publications*, vol. iv (Leyden, 1912).

MAIFELD. See CHAMP DE MARS.

MAIGNAN, mȧ′nyäɴ′, ALBERT (1846–1908). A French decorative and historical painter. He was born at Beaumont (Sarthe) and studied under Noël and Luminais. He received many awards at the Salon, including the medal of honor in 1892, and was given the cross of the Legion of Honor in 1895. Although the influence of the Academic school is occasionally manifest in his work, the best of it is characterized by harmonious color, poetic imagination, and careful draftsmanship. Such are his paintings "Homage to Carpeaux" (1892, Luxembourg), "The Voices of the Tocsin" (Amiens Museum), and the "Green Muse." Among his best historical compositions are: "Dante Meeting Countess Matilda" (1881, Amiens Museum); "Assault on Pope Boniface VIII at Anagni" (Metropolitan Museum, New York); "Louis IX Consoling a Leper" (Angers Museum); "Carlo Zeno" (Lille Museum). His decorative works include the ceiling and panels of the foyer of the new Opéra-Comique, Paris, the cupola of the chapel commemorating the fire of the Bazar de Charité, and designs for the Gobelin tapestries.

MAI′GRE. A fish. See MEAGRE.

MAIKOP, mī′kŏp. A town in the territory of Kuban, Caucasia, situated on a branch of the main railroad line to Baku, 93 miles southeast of Ekaterinodar, the capital (Map: Russia, F 6). It is a growing town and carries on a brisk trade in the agricultural products of the fertile region in which it is situated and in oil from the local wells, which are very productive. Pop., 1897, 34,191; 1912, 45,089.

MAIKOV, mī′kôf, APOLLONIUS NIKOLAIEVITCH (1821–97). A Russian poet, born in Moscow. He was the son of a painter and was educated at St. Petersburg University and, for an artistic career, in Italy. Later he was made a government censor of foreign publications and became a Panslavist. He translated Neo-Greek and Old Slavonic poems, published a volume of original verse in 1842, two lyrical dramas, *Tri Smerti* (Three Deaths) and *Dva Mira* (Two Worlds, contrasting Christian and pagan Rome), and such epics as *Savonarola*, *Clermont Cathedral*, *The Queen's Confession*, and *The Princess*, which was his best effort. Maikov drew his inspiration from the Greek and Roman classics, from mediæval and modern romance, and from the older and more recent Russian history. His complete works were published in St. Petersburg (4 vols., 7th ed., 1901).

MAIKOV, mī′kôf, VALERIAN NIKOLAIEVITCH (1823–47). A Russian social philosopher and literary critic. After an excellent home education (the famous Goncharov was one of his tutors), he entered the faculty of law at St. Petersburg University, where one of his special interests was political economy. His first important article was *On the Relation of Production to the Distribution of Wealth* (1842). He also participated in the compilation of a noteworthy *Pocket Dictionary of Foreign Words Entering into Russian* (2d ed., 1845–46), which might have played the part of a *Dictionnaire philosophique* in Russia, had it not fallen under the ban of censorship. His uncompleted work entitled *The Social Sciences in Russia*, which appeared in the *Finnish Courier*, again displayed his wonderful grasp of political and sociological science. Literary criticism he essayed for the first time in 1846, when, in an article on the poet Koltsov, he boldly challenged some well-known canons of art accepted by the greatest critic of his time, Belinsky (q.v.). A year later, at 24, he died of apoplexy.

Maikov's special distinction as a social philosopher lay in his early attack on the political economists of Adam Smith's school for their study of wealth as an abstract fact and not as a social factor. Being averse to metaphysics, he was especially drawn to the philosophy of Auguste Comte (q.v.). He was the first, too, in Russia to advocate profit sharing for labor, while his views on art curiously forestalled those of Guyau (q.v.). In these and other respects Maikov very early acquired those Western ideas which were to revolutionize Russian thought. Only his premature death prevented him from developing them at length.

MAILÁTH, moi′lät, JÁNOS, COUNT (1786–1855). An Hungarian poet and historian, born at Pest. He studied at Erlau and Raab and was for a time chancery councilor at Pest. This post he lost in 1848 and after seven years of literary labor at Vienna and Munich committed suicide by drowning, with his daughter, in the Starnberger See. His works include: *Gedichte* (1824); *Magyarische Sagen und Märchen* (1825; 2d ed., 1837); a translation of some of Kisfaludy's poems (1829); a valuable edition of the Kalocsa Codex, containing several poems in Old High German; and the historical works *Der ungarische Reichstag von 1830* (1831), *Geschichte der Stadt Wien* (1832), *Geschichte des österreichischen Kaiserstaates* (1834–50), and the *Geschichte der Magyaren* (1828–31), the most valuable of his productions, with two supplementary volumes (1854).

MAILDUN, mäl′dōōn, **MAELDUIN,** or **MAELDUNE.** The hero of an ancient Irish romance known as *The Voyage of Maildun*. It is one of a group of Imrama, or voluntary sea expeditions, of which the *Voyage of Saint Brendan* (q.v.) is equally well known. Maildun was the son of Aillill of the Edge of Battle, an illustrious man of the tribe of Owenaght of

Ninus in the County of Clare by the sea. Before the hero's birth, his father had been slain by a band of robbers who had come over the sea. When Maildun had grown up he set forth in a triple-hide curragh (a canoe made of a framework of wood covered with skins) in search of his father's murderer. In his voyage on the western sea for three years and seven months he visited the island of huge ants, red-hot animals, burning places, the isle of the blest, and other marvelous places. He found his enemy, whom he forgave for the hospitality accorded him after so many perils. The text exists in a redaction of the eleventh century, but the story itself probably goes back to the eighth century. The story is beautifully told by Tennyson in the *Voyage of Maeldune.* For a prose translation, consult P. W. Joyce, *Old Celtic Romances,* translated from the Gaelic (3d ed., New York, 1898). A French version was published by F. Lot in d'Arbois de Jubainville's *Cours de littérature celtique,* vol. v (Paris, 1892). Consult also Nutt and Meyer, *The Voyage of Bran* (2 vols., London, 1895–97).

MAILED CAT. See Catfish.

MAILLET, mȧ'yā', Jacques Léonard (1823–94). A French sculptor, born in Paris. He was a pupil of Pradier and won the Prix de Rome in 1847. His "Agrippina and Caligula" (1853) was the first of his groups to gain recognition; his "Springtime of Life" was at the exposition of 1855; and his other works include: "Agrippina Bearing the Ashes of Germanicus" (in the Garden of the Luxembourg), which was in the exposition of 1867, and "The Satyr and Love," shown in the exposition of 1878. There are decorative groups by him in the courtyard of the Louvre, on the Opera House, and in the churches of St. Clotilde, St. Leu, and St. Séverin in Paris. He also erected a monument to the Bonaparte family at Ajaccio.

MAILLY, William (1871–1912). An American Socialist and journalist, born in Pittsburgh. He was educated in English and Scottish schools; worked in the mines of Illinois and Alabama; and in 1894 became state secretary of the United Mine Workers' Union of Alabama. He was associate editor of the Birmingham *Labor Advocate* (1895–96) and of the *Worker,* New York (1901 and 1906–07), editor of the Nashville *Journal of Labor* and the Haverhill (Mass.) *Social Democrat* (1899–1900), and managing editor of the New York *Evening Call* (1908–09). He served as an organizer of the Social Democrat (now Socialist) party in New York and Chicago in 1898, as secretary of the National Socialist Convention at Indianapolis in 1901, and as organizer and secretary of the Socialist party of Massachusetts in 1902. He was national secretary of the Socialist party in 1903–05 and a member of the National Executive Committee in 1905–06, and he managed the Socialist presidential campaign of 1908.

MAIL-SHELL. A chiton. See Chiton.

MAIMAICHEN, mī'mī'chĕn', or Maimatchin, "to buy and sell place," i.e., trade settlement. The name of two Chinese towns in Mongolia. One is situated 2½ miles east of Urga and was established in the early eighteenth century to further Chinese trade. It was originally a stockaded inclosure with six gates, which are still closed at sunset. A group of Mongol suburbs now surround it. Pop., 4000 to 5000, of whom 1200 to 1500 are Chinese. The other town is situated on the Russian frontier, opposite Kiakta, and has but few permanent residents, most of them being Chinese merchants who come there on business (Map: Chinese Republic, J 2). This town also has a palisade and has two fine temples. Its trade has greatly decreased owing to the Siberian and Manchurian railways, which have seriously diminished the value of the Mongolian caravan routes.

MAIMANA, mī'mȧ-nä'. A town of Afghanistan. See Maimene.

MAIMATCHIN. See Maimaichen.

MAIMBOURG, măn'bōōr', Louis (1610–86). A Roman Catholic historian and polemical writer. He was born in Nancy, France, and became a Jesuit in 1626. As he was an earnest Gallican, the Pope in 1682 secured his dismissal from the Jesuit Order. He died in Paris, a pensioner of Louis XIV, Aug. 13, 1686. His historical works appeared in Paris in 12 volumes in 1686; his polemical works against Protestantism in 1682. English translations were made of *The History of the League* (1684); *The History of the Holy War* (1686); *An Historical Treatise of the Foundation and Prerogatives of the Church of Rome and of her Bishops* (1685); *The History of Arianism* (1728); but his works lack historic accuracy. Several of his books are upon the papal Index. Consult Reusch, *Der Index der verbotenen Bücher,* vol. ii (Bonn, 1883–85).

MAIMENE, mī'me-nä', or **MAIMANA.** A town in north Afghanistan (Map: Afghanistan, L 5), about 180 miles northeast of Herat. Previous to 1874 it was the capital of an independent khanate of the same name, and an important commercial centre, with a population estimated at 60,000. In that year, however, the city was captured and a large part of its inhabitants massacred after a siege of six months by the Afghans, who annexed the khanate to their territory. The town has dwindled to a village of about 2000 inhabitants.

MAIM'ING (from *maim,* from OF. *mehaigner, mahaigner,* to maim, doublet of *mayhem;* possibly connected with Bret. *machaña,* to mutilate, or with OHG. *mangōn, mangalōn,* Ger. *mangeln,* to lack, Eng. *mangle*). A modern statutory offense, generally consisting in the infliction of a permanent physical injury on man or beast. In England the term is employed in the sense of mayhem (q.v.) when applied to injuries to human beings; but when applied to malicious damage to cattle or other animals (see Malicious Damage Act, 1861, 24 and 25 Vict., c. 97, §§ 40, 41) it is used in the popular sense of mutilating. It bears this broader signification in most statutes in the United States. The offense is generally declared to be a felony when committed against human beings or cattle, and a misdemeanor when against other animals than cattle. Maiming one's self to escape the performance of some legal duty, or in order to excite sympathy and obtain alms, is punishable under many modern statutes. Consult Bishop, *Commentaries on the Law of Statutory Crimes* (3d ed., Chicago, 1901), and Archbold, *Pleading, Evidence, and Practice in Criminal Cases* (23d ed., London, 1905). See Mayhem.

MAIMON, mī'môn, Salomon (1754–1800). A Jewish German philosopher, born in Lithuania. He studied medicine in Berlin, but finally devoted himself to the Talmud, with promise of great ability; in 1770 he broke with orthodox Judaism by a critical commentary on the *More Nebukhim* of Maimonides. In Berlin, where he went in 1773, he became interested in Wolff's metaphysics, and was well received by Mendelssohn. After 1788, when he became acquainted with Kant's views all his philosophizing started from Kant's results. Maimon's most important work was the critical *Versuch über die Transcendentalphilosophie* (1790), which had great influence in philosophical circles. In this work he criticizes Kant for certain inconsistencies and reaches the view that a priori knowledge holds not of experience but in the realm of logic and mathematics. Among his other works mention may be made of *Versuch einer neuen Logik* (1797) and of *Kritische Untersuchungen über den menschlichen Geist* (1797). His autobiography, edited by Moritz in 1792, was translated into English by Murray (1888). Consult Witte, *S. Maimon* (Berlin, 1876).

MAIMONIDES, mī-mŏn′ĭ-dēz, properly Moses ben Maimon ben Joseph, Ar. Abu Amram Musa ibn Maimun Obeid Allah al Kortobi (1135–1204). A great Jewish scholar and philosopher. He was born at Cordova, March 30, 1135. Little is known of his early life. He received his first instruction from his father, himself a learned man, and later devoted himself to the study of Greek (Aristotelian) philosophy, the science of medicine, and theology, under the most distinguished Arabic masters of the time. When Abd al Mumin, the Almohade ruler, captured Cordova in 1148 (see Almohades), all Jews and Christians residing there were forced to embrace Islam or emigrate. Maimonides' family outwardly adopted the Mohammedan faith, or rather renounced the public profession of Judaism, but after a time, finding no sign of a change, resolved to emigrate. In 1159 they were at Fez, in 1165 at Acre, and thence by way of Jerusalem they proceeded to Cairo, where the father died. Maimonides' great knowledge of medicine soon gained him the position of physician to Saladin, the Sultan of Egypt, and by virtue of his rabbinic learning in 1177 he became rabbi of Cairo. He died Dec. 13, 1204. His body was carried to Tiberias and in course of time his tomb became a place of pilgrimage. Maimonides' importance for the religion and science of Judaism and his influence upon their development gained for him the title of a "second Moses." His activity extended over the range of Jewish studies—theology, exegesis, and philosophy. Imbued with the spirit of Greek speculation, and acquainted with the best of Arabic thought, he endeavored to explain the Bible by the light of reason, and was the founder of a rational exegesis. When literal interpretation seemed to jar upon the feeling of reverential awe due to the Most High, he did not hesitate to substitute an allegorical interpretation. The most striking feature of his philosophical system is its close similarity to that of Averroës. It is a grand attempt to reconcile rabbinic Judaism with the prevailing Aristotelian system of thought as modified by Arabic philosophers. He differs from Aristotle, however, in maintaining that creation by the divine will proceeded from nothing (*creatio ex nihilo*). He held to the freedom of the will, and condemned a life of asceticism, or dreamy albeit pious contemplation. He taught that the body as well as the soul should be developed and cared for, and hence the study of natural science and medicine is a matter of prime necessity. The soul, and the soul alone, is immortal, and the reward of virtue consists in its—strictly unbodily—bliss in a world to come; the punishment of vice is the loss of the soul. Maimonides' first important work was an Arabic commentary on the Mishna, called by him *Siray* (Illumination) and finished in 1168. It was translated into Hebrew, and for more than five centuries has been deemed so essential a part of the Talmud itself that no edition of the latter is considered complete without it. This was followed by the "Book of Precepts," in Arabic, which is to be considered as an introduction to the gigantic work which followed in 1180, in Hebrew, under the title *Mishne Thora* (Second Law; also called *Yad ha-khazaka*, the Strong Hand). It is a minute and systematic presentation of the Jewish law as developed by the Talmud, and to it he devoted 10 years of his life. The summit of his renown, Maimonides attained in his Arabic *Dalalat al-hairin* (Heb. *More Nebukhim*, Guide of the Perplexed), a philosophical and rationalistic work on exegesis, finished c.1190, which led to a long and bitter contest between the orthodox and liberal in Judaism. His attempt to systematize the Talmudic precept also aroused opposition; and one result of it, unforeseen by himself, was to increase the punctiliousness in carrying out ceremonial observances. It was felt also that there was a lack of consistency between Maimonides the philosopher and Maimonides the theologian, and it is indeed difficult to reconcile his rationalistic exegesis and his untrammeled philosophical speculation with his attitude towards the minute ceremonies of rabbinic Judaism. Maimonides' minor works include medical, mathematical, logical, and other treatises, legal decisions, theological disquisitions, etc. As early as the thirteenth century portions of his books in Latin translation were in use in European universities, and the *Guide of the Perplexed* was followed to a certain extent by Albertus Magnus and Thomas Aquinas. There is an English translation of the *Guide of the Perplexed* by Friedländer (3 vols., London, 1885). The Arabic of the original with French translation was published by Munk (Paris, 1856–66). Consult: Joel, *Die Religionsphilosophie des Mose ben Maimun* (Breslau, 1859); Grätz, *History of the Jews*, vol. iii (Eng. trans., Philadelphia, 1873); Kaufmann, *Geschichte der Attributenlehre* (Gotha, 1877); Karpeles, *Geschichte der jüdischen Litteratur* (Berlin, 1886); Bacher, *Bibelexegese Moses Maimunis* (Strassburg, 1897); Yellin and Abrahams, *Maimonides* (Philadelphia, 1903), with bibliography; Neumark, *Geschichte der jüdischen Philosophie des Mittelalters*, vols. i, ii (Berlin, 1907–10).

MAIN, mīn. A river of Germany and the largest right affluent of the Rhine. It rises in two head streams in the Fichtelgebirge in northeast Bavaria and flows in a westerly direction through the northern part of Bavaria and then on the borders of Hesse and the Prussian Province of Hesse-Nassau, joining the Rhine at Mainz (Map: Germany, C 4). The entire length of the Main is 307 miles, and it is navigable from its confluence with the Regnitz, a distance of about 205 miles. The principal towns on its banks are Würzburg and Frankfort. The Main, in spite of its length, is not very important from a commercial point of view, owing to frequently occurring shoals, the tortuousness of its course, and the small volume of water in summer time, so that at Würzburg it serves for little except a considerable flotation of timber. It has, however, been canalized between Mainz and Frankfort, so as to admit vessels of 1000 tons, and its waters communicate with those of the Danube by means of the Ludwigs-Kanal with a depth of 4.2 feet.

MAINA, mī′nȧ. See MAYNA.

MAINAN, mī′nan. A linguistic stock of Ecuador, South America, included in which is probably the Laman, formerly listed as a separate stock. Consult D. G. Brinton, *Studies in South American Native Languages* (Philadelphia, 1892), under "Jivaro" and Beuchat and Rivet in *Zeitschrift für Ethnologie*, vol. xli (Berlin, 1909).

MAINDRON, măɴ′drôɴ′, GEORGES RENÉ MAURICE (1857–1911). Pseudonym, RENÉ GERBERT. A French historical novelist. The French government sent him on various scientific missions to New Guinea, Indo-China, etc., and made him a Knight of the Legion of Honor. At various times he held office in a number of scientific societies. He married Miss Helen Heredia, daughter of the poet José María de Heredia. His writings include: *Les papillons* (1887); *Les armes* (1891); *Les chasseurs d'oiseaux du paradis* (1891); *Un capitaine d'aventurers* (1891); *Les hôtes d'une maison parisienne* (1892); *Les musées d'Espagne* (1892); *Les briseurs d'image* (1892); *Manuel du naturaliste* (1894); *Le tournoi de Vauxplassant* (1895), crowned by the French Academy; *Blancador l'avantageux* (1900); *L'Art indien* (1900); *Monsieur de Clirambon* (1904); *Le meilleur parti* (1905), comedy; *L'Arbre de science* (1906); *L'Inde du sud* (1907); *Le carquois* (1907); *La gardienne de l'idole* (1910); *Ce bon M. de Véragues* (1911).

MAINE, mān. One of the ancient provinces of France, bounded on the north by Normandy, on the east by Orléanais, on the west by Brittany, and on the south by Anjou and Touraine. It corresponds approximately to the modern departments of Sarthe and Mayenne. The crown obtained final possession of it in 1481, after the house of Anjou had become extinct. The capital was Le Mans.

MAINE (called "The Province or Countie of Mayne" in the charter granted by Charles I in 1639, because regarded as part of "the Mayne land of New England"). A North Atlantic State of the United States, belonging to the New England group, and the most northeasterly State of the Union. It lies between lat. 43° 4′ and 47° 28′ N. and between long. 66° 57′ and 71° 7′ W.; it is bounded on the northwest by the Canadian Province of Quebec, on the northeast by the Province of New Brunswick, on the southeast by the Atlantic Ocean, and on the west by the State of New Hampshire. Its extreme length is a little over 300 miles, its extreme width 185 miles, and its total area 33,040 square miles, the land amounting to 29,895 square miles. Maine is nearly as large as all the rest of the New England States combined, and is thirty-eighth in size among the States of the Union.

Topography. The surface of Maine is in general moderately hilly, becoming mountainous in the west and north. The elevation rises from the coast northward and from east to west towards the interior. Along the coast in the southwest corner the surface falls into low, flat, and even marshy land, and the country maintains its low and generally level character as far as the Kennebec River. East of the Kennebec the coast region rises to abrupt and bold elevations of 1000 to 1500 feet. The general slope of the State is determined by the main plateau, which crosses it in a northeasterly direction and is the continuation of the Appalachians. This system appears here only in somewhat isolated heights which, while preserving the continuity of the Appalachians, can scarcely be called a mountain range. The height of this divide varies from 2000 feet above sea level on the west, where it enters the State, to 600 feet at its eastern extremity, where it dies away in the Aroostook region on the border of New Brunswick. The most prominent peak is Mount Katahdin, 5200 feet high. Nearer the west border stand Mount Abraham, 3388 feet, and Mount Bigelow, 3600 feet.

This fringelike coast, with its tasseled edge of bold promontories and rocky islands, has given rise to the appropriate appellation of "hundred-harbored Maine." Although less than 200 miles long, measured in a straight line, such are its sinuosities that it presents a seaboard frontier of nearly 3000 miles. The fiord-like harbors are the result of the drowning of the river valleys scored out by glacial action and extending seaward far beyond the present shore line. This has provided Maine with excellent natural harbors, perfectly protected by the islands, but suffering from a serious disadvantage in the great rise and fall of the tides and the resulting swift currents. At Portland the tide rises 11 feet, increasing eastward. Yet in spite of this disadvantage the coast between Portland and Eastport contains proportionately the greatest number of good harbors to be found anywhere along the coast of the United States.

There are upward of 1600 lakes and ponds, aggregating a total area of over 3145 square miles, or one-eleventh the total area of the State. They lie for the most part in the elevated plateau region and are of great natural beauty. The most noted are: Moosehead Lake, 120 square miles in extent, the largest inland body of water in New England and the source of the Kennebec River; the Rangeley Lakes, with an area of 90 square miles, the headwaters of the Androscoggin River; Chamberlin Lake, supplying the St. John; and Chesuncook Lake, connected with the Penobscot River.

More than 6000 streams lace the surface of the State, with waters of unusual purity. The largest rivers of Maine are naturally those of the south slope. The chief of these are the Saco, Androscoggin, Kennebec, Penobscot, Union, and St. Croix, the last named on the east boundary. The St. John River traverses the northwest corner of the State and forms part of the boundary with New Brunswick. They are of little value for commerce, being navigable only a few miles inland—the Kennebec 26 miles to Augusta; the Penobscot 27 miles to Bangor. They rise at high elevations, and their precipitous character offers the explanation of their value as sources of water power. The power available for industrial purposes is enormous, the Androscoggin alone having developed over 70,000 horse power. Besides, the lakes in connection with these rivers furnish reservoirs for the storage of water, and thus make possible a uniform and constant supply of power through all the year. It is estimated that about 2,000,000 horse power is available. This is utilized especially at the falls which characterize most of the rivers, and which are due to the tilting and folding of the extremely indurated sedimentary strata alternating with unyielding granite beds that cross their path.

Geology. Maine has had a very complex geological history. In pre-Cambrian time the

State was crossed by two great mountain ranges. One extended along the northwest boundary through the White Mountains to Long Island Sound east of the Connecticut River; the other extended northeast, along the coast. These mountains were much folded, largely gneissic and schistose, and they were worn down to base level in later Paleozoic time. Through the centre of the State, between these two ranges, a long gulf extended from Gaspé peninsula to the southwest. By the end of Devonian time this trough was filled with sediments from the aging mountains, only to be uplifted, crumpled, and somewhat metamorphosed, again worn to base level and depressed, allowing Carboniferous deposits to be laid down unconformably upon all the older beds. It was uplifted and again worn to base level in Cretaceous time, since which the region has been broadly lifted into a plateau of low elevation and again dissected. The Pleistocene ice sheet covered the State entirely, discharging its marginal ice into the sea. The effect of glaciation was to denude the higher lands, accentuate the river valleys, create many lake basins, and leave the surface strewn with a coating of till. Since Pleistocene time there has been a considerable subsidence, resulting in the submergence of the coastal lowlands and converting the higher hills and ridges into a fringe of islands and the drowned valleys into fiords. The latest crustal movement has been a very slight uplift along the coast, uncovering small plains of marine clays which interlock with the rocky headlands. This same slight uplift has revived the rivers, furnishing very valuable water power at the bay heads.

Climate. Maine lies in the heart of the temperate zone, being practically bisected by the forty-fifth parallel of north latitude; yet in climate it ranks as boreal in the northwestern part, and the southeastern part is only a region of transition into the austral zone—a region of overlapping floras and faunas. The winter is very severe, except in a narrow strip along the coast. The summers are never hot. The mean temperature for January is 20° F. in the south and 10° F. in the north. In July the mean temperature is 65° F. in the north and 70° F. in the south. There is a wide range of temperatures through the year, the average maximum shade temperature of 90° F. occurring all along the coast to Eastport. The anticyclones and north winds of winter bring an average minimum of 20° F. below zero to Eastport and Augusta, while the vicinity of Mount Katahdin records an average minimum of 30° below zero. The weather is subject to sudden falls in temperature in short periods because of the frequent passage of cyclonic and anticyclonic centres and the subjection of the State to alternate oceanic and continental influences. The southern counties have a growing season of less than six months, and the northern counties of only about five months. The average annual rainfall for the whole State is 40 inches, very evenly distributed throughout the year, though there is a maximum precipitation in the late summer and autumn. There is an average annual snowfall at the coast of 60 inches, increasing rapidly to the north and west to over 110 inches. The relative humidity for the whole State is above 70 per cent, though the absolute humidity is rather low, on account of low temperatures. The normal wind direction for January is northwest, and for July is southwest. The State lies in the zone of maximum cyclonic frequency.

The cool summers, the lakes, the forests, and the rocky seaside attract multitudes of summer tourists.

The coast and lakes are lined with summer cottages.

Some of the resorts, notably Bar Harbor, on the eastern side of Mount Desert (q.v.), are among the most popular of the American summer resorts.

Soils. The soils of Maine, with the exception of the Pleistocene marine clays along the coast, are almost wholly glacial. A most interesting series of kames traverses its southeastern plateau, having their northerly termini generally along the line of the divide, separating the waters flowing into the Atlantic from those of the northeastern plateau, which discharge into the St. John River basin. The synclinal kame plains between these "horseback" ridges are usually very fertile, especially those of the southeastern counties of Hancock and Washington. Along some of the rivers and lakes and in many old lake bottoms, long since filled up or drained out, there are also alluvial plains of great fertility. The higher outcrops of the crystalline old land are largely denuded of all soil, while the whole surface of the State is more or less strewn with glacial débris. The drift is in places arable, though in wide areas it is unsuited for agriculture. The character of the soil and the large supply and even distribution of rainfall have been determining factors in making the State a rich forest region.

Mining. Maine has little distinction as a mineral-producing State. Granite, the principal product, contributes one-half of the total mineral production. The quarries from which much of the stone is cut are directly on the coast. This lessens the cost of stone at the shipping point and enables it to be sold for a comparatively low price. In 1913 the total value of granite of all kinds produced was $1,790,279. Of this total the building stone produced was valued at $841,168 and the monumental stone at $56,413. The residue was made up of paving, crushed stone, curbing, and flagging. Maine ranks third in the production of granite among the States, Vermont and Massachusetts ranking first and second respectively. Another important stone product is slate, in the production of which Maine ranks third. In 1913 the value of the output was $323,998, entirely quarried in Piscataquis County. There is also a considerable production of limestone, most of which, exclusive of that burned for lime in the State, is used by paper manufacturers. The value of lime produced in 1913 was $906,604. The crystalline rocks produce many rare minerals, one of which, tourmaline, is obtained in Oxford County in larger and more beautiful crystals than anywhere else in the world. Maine leads in the production of feldspar, the value of which in 1913 was $347,499. The mineral waters are of national repute, of which in 1913 there were sold 1,174,262 gallons. Clay, sand, and gravel are also produced in commercial quantities. The total value of the mineral products in 1913 was $4,429,584.

Agriculture. The rugged and broken surface of Maine, characteristic of the New England States, does not admit of extensive agricultural development. For the most part the soil is sterile, though in the river valleys, particularly that of the Aroostook River, the soil is very fertile. This section is devoted almost entirely to the raising of potatoes of such superior quality that most of the product is used for seed both in America and abroad. In 1910, 6,296,850 acres out of a total land area of 19,132,800 acres were in farms, of which there numbered 60,016. In that year there were 2,360,657 acres in improved land in farms, and the average acreage per farm was 104.9. The total value of farm property, including land, buildings, implements and machinery, domestic animals, poultry, and bees, was $199,271,998 in 1910. The average value of all property per farm was $3,320 in 1910, while the average value of land per acre was $13.73.

Of the total number of farms in 1910 (60,016), 57,453 were operated by owners and managers and 2563 by tenants. It will be noted from this that the percentage of farms operated by tenants is unusually small. Of the total farm operators in 1910, 55,014 were native whites, while 4973 were foreign-born whites and 29 were negroes and other nonwhites. Of the foreign-born white farmers, 3628 were born in Canada.

The following table shows the acreage, value, and production of the principal crops in 1914 as estimated by the United States Department of Agriculture.

PRODUCT	Acreage	Prod. bu.	Value
Corn	16,000	736,000	$648,000
Wheat	3,000	81,000	88,000
Oats	141,000	5,781,000	3,295,000
Barley	5,000	150,000	122,000
Buckwheat	12,000	348,000	209,000
Potatoes	130,000	33,300,000	11,154,000
Hay	1,230,000	* 1,414,000	18,523,000

* Tons.

The general character of agriculture is indicated by the fact that in 1909 only 7.9 per cent of the total value of crops was contributed by cereals, while nearly two-fifths was contributed by hay and forage and nearly one-third by potatoes and other vegetables. The total value of crops in 1909 was $39,318,000. The leading crops, judged by value, are hay and forage, potatoes, oats, and corn. As elsewhere in New England, the influence of Western competition has obliged Maine farmers to give up cereal farming in a large measure. Oats is the principal cereal grown. In 1909 over one-half the total acreage of potatoes was in Aroostook County. Of the potatoes commercially grown, the greater quantity is produced in Aroostook and Penobscot counties. In the production of potatoes improved methods are used, so that the yield per acre is the highest of all the States. In 1909 it was 210.3 bushels, while in 1914 the estimated yield per acre was 260 bushels, which was about 92 more than its nearest competitor, Vermont.

In 1909 the total acreage of potatoes and other vegetables was 161,087, and their value was $12,378,000. Excluding potatoes, the acreage of vegetables was 25,288, and the value $2,153,000. Many parts of the State are well adapted to the growing of orchard fruits, especially apples. There were produced, in 1909, 3,636,181 bushels of apples, valued at $2,121,816. Other fruits produced in smaller quantities are pears, cherries, plums, and prunes. The most important of the small fruits is the strawberry, of which 1,626,250 quarts, valued at $168,847, were produced in 1909.

Live Stock and Dairy Products. Stock raising is not a leading industry, but some of the horses raised are of superior quality and are in great demand for breeding and other purposes. The total value of all live stock on farms in 1910 was $23,989,560. The estimated number of animals on the farms on Jan. 1, 1915, was as follows: cattle, other than milch cows, 101,000, valued at $2,636,000; milch cows, 157,000, valued at $8,478,000; horses, 113,000, valued at $16,498,000; sheep, 165,000, valued at $741,000; swine, 95,000, valued at $1,492,000. The dairy cows on April 15, 1910, numbered 156,819. The milk produced in 1909 was 56,026,334 gallons. From this was made 13,299,229 pounds of butter, valued at $3,786,054. The total value of milk, cream, butter fat, butter, and cheese made in 1909 was $8,079,692. The total number of fowls of all kinds in 1910 was 1,735,962, valued at $1,131,921.

Fisheries. The State ranks second among the New England States in the value of its fisheries and first in the number of men engaged in the fishing industry. Of all fishery products, the most important in point of value is lobster, this being more important in Maine than in all the other New England States combined. In 1908, the latest year for which complete statistics are available, 9,929,200 pounds of lobster, valued at $1,269,450, were taken. Next in point of value was cod, of which 20,010,800 pounds, valued at $438,880, were caught. Herring, the third fish in point of value, was taken to the amount of 92,985,200 pounds, valued at $419,980. Herring fishing is more important here than in any other New England State. In several of the rivers salmon of unusual quality is taken, and the salmon fishery, although comparatively small, is the largest on the Atlantic coast. Other fish taken in large quantities are haddock, clams, scallops, hake, pollock, and swordfish. The canning of small herring as sardines is an important industry, especially at Eastport, and the preparation of smoked herring is of considerable importance. The total value of the fisheries for the year ending Dec. 31, 1908, was $3,256,580. There were 5004 independent fishermen engaged, with 1857 employees. The number of vessels employed was 576, valued at $817,463.

Forest Products. Maine was for many years one of the leading States of the Union in the extent of wooded area and the annual value received from the forest products. There still remain large areas of wooded land which are practically untouched. The forests cover largely the interior and northern portions, the coast and lower valleys being generally cleared. The land rapidly reforests, and since most of it is not well suited to cultivation, reforestation is extensive. The primeval forests of white pine which gave the State the name of Pine Tree State have nearly all disappeared, but the second growth is being used to a large extent. Spruce forests are the most extensive.

The relative abundance of different trees in Maine at the present time is indicated roughly by some statistics from the Thirteenth Census. In 1909 there were 1243 saw mills in the State, with the following production of lumber, laths, and shingles in M feet, B. M.: spruce, 421,297; white pine, 383,551; hemlock, 109,581; birch, 62,812; balsam fir, 50,491; oak, 18,554; maple, 16,714; cedar (mostly arbor vitæ), 15,140; yellow pine (mostly pitch pine), 13,474; beech, 9638; basswood, 4123; ash, 2572; cottonwood, 2012; elm, 910; tamarack, 420; all others, 276. Total conifers, 993,954; total hardwoods, 117,611; grand total, 1,111,565, valued at $18,913,678. Lath amounted to 337,086 thousands, and the shingles to 598,131 thousands. In 1909 Maine ranked first among the States in its cut of spruce. It was also first in the cut of white pine.

In the same year there were used for pulp wood by Maine paper mills 552,032 cords of spruce grown within the State, 119,550 cords of poplar (aspen), 10,954 of hemlock, 1615 of balsam, 781 of pine, and 341 of other woods. For details of the use of the forests in the manufacture of wood pulp and paper, see the section on *Manufactures* below.

In addition to the statistics of forest products given above, there were produced in 1909, on the farms of the State, forest and timber products valued at $5,573,763. Of this amount $870,525 were received for standing timber.

Manufactures. Transportation facilities of Maine are good, and important manufacturing centres are accessible by rail, while good harbors and navigable rivers afford excellent means for water transportation. The following table gives the most important data relating to manufactures in 1909 in comparison with 1904.

Five industries greatly predominate in importance. They represent approximately two-thirds of the average number of wage earners, value of products and value added by manufacture. There is a considerable diversity in the manufacturing activities. The manufacture of paper and wood pulp is the leading industry, measured by value of products. In 1909 Maine produced 12.7 per cent of the total value of paper and wood-pulp products for the country. The large forests of pulp wood have resulted in the importance of this industry. To manufacture the wood into pulp and paper, some of the largest mills devoted to these purposes hitherto erected are employed. In 1909 these mills consumed 903,962 cords of pulp wood, or nearly three times the quantity used in 1899. Of this wood, 718,532 cords were spruce, 123,052 were poplar, 10,954 were hemlock, and 2737 were of other species. The quantity of all kinds of paper produced in 1909 was 574,215 tons. The largest quantity of paper is for newspaper purposes. This in 1909 was valued at $11,424,388. Book paper was valued at $8,079,299. The second industry in point of value of products is that related to the manufacture of lumber and timber. For further information in regard to this industry, see the paragraph *Forest Products* above. Textile industries are third, of which the manufacture of cotton and woolen goods is the most

COMPARATIVE SUMMARY FOR 1909 AND 1904 *

THE STATE — ALL INDUSTRIES COMBINED AND SELECTED INDUSTRIES

INDUSTRY	Census	Number of establishments	PERSONS ENGAGED IN INDUSTRY		Capital	Wages	Cost of materials	Value of products	Value added by manufacture
			Total	Wage earners (average number)	Expressed in thousands				
All industries	1909	3,546	88,476	79,955	$202,260	$37,632	$97,101	$176,029	$78,928

	1904	264	5,966	5,346	9,154	2,441	6,011	10,842	4,831

important. The canning and preserving of vegetables, fruits, and fish form also an industry of importance. The total number of cases of corn canned in 1909 was 792,158, valued at $1,320,223. The canned fish amounted to 90,445,752 pounds, valued at $4,812,739. Of these, sardines alone were $4,609,224. The most important of canned fruits are apples, of which 75,540 cases, valued at $122,791, were canned in 1909.

Shipbuilding was once one of the leading industries, but as the building of ships ceased to depend upon forest products and the use of steel in vessel construction increased, the industry declined. A vessel was built in the State as early as 1608, and for a long period Maine held first rank in shipbuilding. At one time there were constructed in the State more than one-half of all the seagoing vessels of the nation. At the present time the industry is carried on chiefly in Bath, once a great centre for the building of wooden ships. That the industry is still of importance is shown by the fact that the value of the product in 1909 was $3,062,000, and that it gave employment to an average of 1755 wage earners.

The wage earners in the factory industries in 1909 were 79,955, of whom 61,420 were males and 18,535 females. The wage earners under 16 years of age numbered 1387, of whom 808 were males. There were no important industries where children under 16 years of age were employed to any considerable extent, with the exception of the cotton mills. The prevailing hours of labor for slightly more than one-half of the wage earners in 1909 were 60 hours a week. This high proportion has resulted chiefly from the more or less general prevalence of the 60-hour week in the cotton and woolen mills and the lumber and canning industries.

There were in 1909 seven cities having a population of over 10,000. These contained 22.4 per cent of the total population and produced 29.2 per cent of the total value of manufactured products. Several of the more important industries, including the manufacture of woolen goods, are carried on chiefly outside of this class of cities. The most important cities and the value of products in 1909 were: Portland, $11,950,367; Lewiston, $10,475,374; Biddeford, $9,001,606; and Auburn, $8,842,629, with 4902, 6788, 5076, and 3452 wage earners respectively. Other cities having a value of product of $3,000,000 or over were Augusta, Bangor, and Waterville. Lewiston and Biddeford owe their importance to the manufacture of cotton goods, and in Auburn the manufacture of boots and shoes is the principal industry. The industries of Portland are diversified and include lumber and timber products, foundry and machine-shop products, and the printing and publishing industry. Further information in regard to these cities will be found under their separate titles in other portions of this work.

Transportation. Portland has one of the best harbors on the North Atlantic coast and is an important seaport for domestic and foreign shipping. Maine is the only one of the New England States in which there was a large railroad construction in the last decade of the nineteenth century. This was chiefly due to the building of the Bangor and Aroostook Railroad, running from Bangor into the northeastern counties. The total steam-railroad mileage in 1913 was 2301. The longest railroads are the Maine Central, with a mileage of 992; the Bangor and Aroostook, 630; the Canadian Pacific, 177; the Boston and Maine, 139; and the Sandy River and Rangeley Lakes Railroad, 105. The building of street and suburban railways has been rapid. The total mileage of electric railways in 1913 was 492. The longest of these is the Lewiston, Augusta, and Waterville Street Railway, with a mileage of 139. Lines of steamships sail regularly between the largest cities of the State and Boston, also between Portland and New York, St. John, N. B., and Halifax.

Banks. On Sept. 12, 1914, there were 69 national banks with loans aggregating $39,391,467; cash, etc., $650,895; capital, $7,740,000; and deposits, $51,650,375. There were, on June 30, 1914, $95,222,151 deposited in 48 savings banks, credited to 236,279 depositors. There were also 45 loan and trust companies with loans of $32,776,909 and deposits of $48,485,526.

Government. The present constitution was adopted in 1819. Two-thirds of both Houses of the Legislature concurring, a proposed amendment to the constitution is submitted to the people in the form of a resolution. This is voted upon on the second Monday in September following its passage, and if a majority of the voters are in favor, the amendment becomes part of the constitution.

Legislative.—The legislative power is vested in a Senate and a House of Representatives. The House of Representatives consists of 151 members, elected by the qualified electors for two years. The Senate consists of not less than 20 nor more than 31 members, elected at the same time and for the same term as the Representatives. The Senate has the sole power to try impeachments. The Legislature convenes on the first Wednesday of January biennially.

Executive.—The supreme executive power is vested in the Governor, who is elected biennially by a plurality vote. A council of seven persons is elected biennially by joint ballot of both Houses of the Legislature, to advise and assist the Governor, but not more than one councilor can be chosen from any senatorial district. A Secretary of State and a Treasurer are also chosen by joint ballot of both Houses at the first session of the Legislature. Each serves for two years, but the Treasurer is not eligible for more than six years' successive service.

Judiciary.—Judicial power is vested in a supreme court and such other courts as the Legislature may, from time to time, establish. Judges and registers of probate are elected by the people of their respective counties by a plurality vote at the annual election. Judges of municipal and police courts are appointed by the executive power in the same manner as other judicial officers and hold office for four years. An Attorney-General is chosen biennially by the Legislature on joint ballot.

Suffrage and Elections.—Every male citizen of the United States of the age of 21 years and upward, excepting paupers, persons under guardianship, and Indians not taxed, having a residence established in the State for a term of three months next preceding any election, is an elector for Governor, Senators, and Representatives; but no person has the right to vote or be eligible for office who shall not be able to read the constitution in the English language and write his name, except any person prevented by physical disability from complying with these requirements, or any person who had a right to vote in 1891 at the time of the adoption of the amendment providing for an educational qualification. Governors, Senators, and Representatives in the Legislature are elected biennially, dating from 1880. In 1907 the constitution was amended to provide for a people's veto through the optional referendum and a direct initiative by petition and at general or special elections. The Legislature of 1911 enacted a direct primary law, but this was superseded as the result of a special election held on September 11 of that year, at which a measure known as the Davies Direct Primaries Elections Law was voted upon in referendum. The Davies law applies to all candidates for congressional, State, and county offices. The measure also included a stringent corrupt-practices provision, determining not only the amount of money which shall be expended by candidates for public office, but also the methods by which it shall be expended.

Local and Municipal Government.—The State is divided into 16 counties, and these into districts, towns, and plantations. Towns not incorporated as cities are governed by boards of selectmen elected at annual town meetings. At the same meetings are passed such provisions and measures for local government as are necessary. Cities and towns have the right to adopt a commission form of government. The first charter providing for this method of government was adopted by the city of Gardiner on Sept. 11, 1911. At the end of 1913 this was the only city in the State which had adopted a commission form of government.

Other Constitutional and Statutory Provisions.—In 1884 an amendment prohibiting the manufacture and sale of intoxicating liquors was adopted by the people and became a part of the constitution in January, 1885. In 1905 there was passed what is known as the Sturgis law. This created an enforcement commission of three, to be appointed by the Governor, and gave them the power of sheriffs to enforce the liquor laws. Husbands are not liable for debts contracted by their wives in their own name, but the latter may be sued for them. A wife may hold real estate and personal estate separately from her husband and may convey or devise the same by will. The employment of children under 14 years of age in manufacturing or mechanical establishments is forbidden. Hunting by unnaturalized foreign-born persons is forbidden. Corporations are required to pay an annual franchise tax of from $5 to $75 in accordance with the amount of capital investment. There is a 58-hour law for women and children in all cotton mills and other factories, except sardine factories and corn shops. The Legislature of 1909 created a State board of arbitration for labor disputes. The Legislature of 1911 created a department of labor and industry. In 1913 the Legislature passed an antitrust act and a public-utilities act, patterned after the Wisconsin statute.

Finance. At the beginning of the fiscal year 1913 there was in the Treasury a balance of $649,303. The total valuation of the State in 1913 was $478,156,044, and the State tax was $2,392,936. The chief expenditures are for education, government officers, and charities and corrections. There is an inheritance tax law which was amended in 1911. There is also taxation of express companies, steam railroads, insurance companies, telephone and telegraph companies, and foreign corporations. The funded debt of the State on Jan. 1, 1913, consisted of one series of negotiable bonds and of several public-debt obligations to public trust funds. The total bonded indebtedness on Jan. 1, 1914, was $569,000. The per capita debt showed a decrease of $8.49 in 1880 to $1.67 in 1912.

Militia. In 1910 there were 151,325 males of militia age. In 1914 the organized force numbered 1512 men, consisting of 108 officers and 1404 enlisted men.

Population. The population of the State at different periods is shown by the following figures: 1790, 96,540; 1810, 228,705; 1830, 399,455; 1850, 583,169; 1860, 628,279; 1870, 626,915; 1880, 648,936; 1890, 661,086; 1900, 694,466; 1910, 742,371. Population on July 1, 1914, was 762,787; 1920, 768,014. The State ranked thirty-fourth in population in 1910. The urban population, including places of 2500 or more, in 1910 was 381,443. There were in that year 1363 negroes. There has been a large immigration of French from Canada, and these congregate for the most part in industrial centres. The total number of native whites of foreign or mixed parentage in 1910 was 134,955. The foreign-born whites numbered 110,133. Of the foreign-born whites, 35,013 were French Canadians and 40,905 were Canadians of native birth. In the extreme northeastern part of the State there are extensive sections in which the population is almost entirely French. These are descended from the French inhabitants of Nova Scotia, who were driven from their homes by the English. There is also a settlement of Swedes in Aroostook County, which for many years has formed a prosperous community known as New Sweden. By sex the population was divided in 1910 into 377,052 males and 365,319 females. The males of voting age numbered 235,727. The largest city is Portland, with a population in 1910 of 58,571. The other large cities, with their populations in 1910, are as follows: Lewiston, 26,247; Bangor, 24,803; Auburn, 15,064; Biddeford, 17,079; Augusta, 13,211; Waterville, 11,458; Bath, 9396.

Education. In 1910 the percentage of illiteracy for all persons of 10 years of age and over was 4.1; among those of native parentage it was 1.4. The total school population (6 to 20 years of age) was 221,271 in 1914, while the enrollment was 146,620, and of these 113,056 attended school. The number of teachers in the elementary schools in 1913 was 6938, and in the secondary schools 670. The average yearly salary of male teachers in the elementary schools was $465.99, and of female teachers $345.93. In the secondary schools the average yearly salary of male teachers was $947.40, and of female teachers $558.08.

Standards of education in Maine have always been high. In 1821 a law was passed requiring every town and plantation to raise and expend not less than 40 cents per inhabitant for school purposes. In 1828 there were set aside by law 20 townships of public land for the establishment of a public-school fund. Prior to 1873 a large number of academies flourished, but in that year provision was made in the Legislature for State aid to towns which maintained schools for free academic instruction. In 1889 towns were authorized to contract with any academy or high school for the tuition of their scholars and to receive the same aid from the State as if they had established a free high school within the town. Town management has taken the place of the district plan of school supervision, and there is a strictly enforced compulsory-attendance law covering the ages from 7 to 15 inclusive. The average elementary school year is 163 school days. In a group of towns in the most northern part of the State, comprising what is known as the Madawaska Territory, is found a peculiar educational situation. The people in this section are descendants of the Acadian exiles who settled in the upper St. John River valley. Since the French language was the universal language of the people, there arose the question of providing for them adequate educational facilities. By an Act of the Legislature of 1863 the towns of Madawaska Territory were given liberal conditions of State aid, with the provision that instruction in all the schools should be given in the English language. No teachers were to be found within the territory who were available for service in the schools. This condition led to the establishment of a Madawaska Training School at Fort Kent, the chief function of which was to be the training of teachers for the common schools of the territory. So well has the school performed the service for which it was established that the English language is now generally spoken and understood among the people. The total enrollment in the secondary schools on July 1, 1912, was 16,467. The total number of free schools receiving State aid in 1912 was 182, and the number of towns maintaining free high schools was 177. There were, in the same year, 49 academies with 4244 students. The total expenditures for public schools in 1912 was $3,151,917.

The Legislature of 1913 passed Acts providing for State certification of all teachers of public schools and for increasing the efficiency of the public schools by retiring teachers of long service with pensions. Provision was also made for better enforcement of child-labor laws and for extension of industrial educational work. The normal schools are Western Normal School at Gorham, Washington State Normal School at Machias, Farmington Normal School at Farmington, Castine Normal School at Castine, Aroostook State Normal School at Presque Isle, and Madawaska Training School at Fort Kent. The institutions for higher education include the University of Maine (see MAINE, UNIVERSITY OF) at Orono, Bowdoin College (q.v.) at Brunswick, Colby College (q.v.) at Waterville, and Bates College (q.v.) at Lewiston. The University of Maine is a State institution, and since the beginning of 1912 admits students from any standard school of the State upon the record of satisfactory completion of subjects required for admission.

Charities and Corrections. The Legislature of 1913 created a State board whose duty is to investigate and inspect the whole system of public charities and correctional institutions and examine into the condition and management of prisons, jails, reform schools, industrial schools of a charitable or correctional nature, etc. The charitable institutions under the control of this body include the Augusta State Hospital, the Bangor State Hospital, the Maine School for the Feeble-Minded at West Pownal, and the Bath Military and Naval Orphan Asylum. The child-saving institutions include the Maine Children's Home Society at Augusta, the Eastern Maine Orphans Home at Bangor, the Children's Aid Society of Maine at Belfast, the Healy Asylum for Boys and the Lewiston and Auburn Children's Home at Lewiston, the Maine Home for Friendless Boys and the Temporary Home for Women and Children at Portland. The correctional institutions include the Maine Industrial School for Girls at Hallowell, the State School for Boys at South Portland, and the Maine State Prison at Thomaston. There are in addition many private charitable institutions in the larger cities. The expenditures for all the institutions in the care of the State in 1913 was $1,102,177. In the child-saving institutions in 1913 there were 962 children. The total number of persons cared for by the correctional institutions in 1913 was 1226. The wife or guardian of the children of any prisoner convicted of desertion and employed at hard labor receives from the State 50 cents a day for the labor of the convict.

Religion. The immigration into the State during recent years, including the large number of French Canadians, has increased the Roman Catholic population until the Roman Catholic communicants number over one-third of the total Church membership. The strongest Protestant denominations in their order are the Baptists, Methodists, and Congregationalists.

History. Maine attracted the interest of explorers early in the sixteenth century. Giovanni da Verrazano sailed down the coast in 1524, Estevan Gómez followed him in 1525, and before the middle of the sixteenth century more than one navigator had sailed up the Penobscot River in search of splendid Norumbega (q.v.), with its columns of crystal and silver. In 1580 John Walker, sailing in the employ of Sir Humphrey Gilbert, led an expedition to Maine, but with no results. The voyages of Gosnold (1602), Pring (1603), and Weymouth (1605) were followed by that of John Smith (1614), who left an account of the country in his *Description of New England.* In 1604 a French expedition under De Monts (see MONTS) planted upon Neutral Island, in the St. Croix River, a colony which was abandoned in the following year. Maine fell within the limits of the grant made to the Plymouth Company by James I in 1606, and in the following year an English expedition sent out by Sir John Popham and Sir Ferdinando Gorges effected a settlement at Sabino Point, at the mouth of the Sagadahoc or Kennebec River. In 1608 the settlement was abandoned, and most of the colonists returned to England. French Jesuits landed on Mount Desert as early as 1608, and in 1613 they were joined by a number of fishermen; but Captain Argall (q.v.) broke up the colony within a short time. In 1622 Sir Ferdinando Gorges and Captain John Mason received from the Council for New England a grant of the territory between the Merrimac and the Kennebec rivers extending for 60 miles inland. The proprietors divided their possessions, the former taking the land east of the Piscataqua River. A colony of fishermen settled on Monhegan Island in 1623, but disappeared three years later. The first permanent settlement in Maine was made at Pemaquid in 1625–26; Agamenticum (York) was founded about the same time, and after 1630 Saco, Biddeford, Port Elizabeth, Portland, and Scarborough sprang up in rapid succession. In 1639 Gorges received a large accession of territory and was confirmed in his old possessions with the title of Lord Palatine, and established a provincial government at York. Before this time the Council for New England had issued many patents covering lands already granted to Gorges, and in the disputes that followed Massachusetts was called in as arbitrator. Taking advantage of the civil war that was then raging in England, the Massachusetts government proceeded to bring Maine under its own authority. In 1652 it annexed all the towns as far east as Casco, basing its right on its charter, which granted it all lands 3 miles north of the source of the Merrimac. By 1660 all Maine west of the Penobscot was reduced, and it was retained in spite of royal orders from Charles II and a grant made in 1664 to the Duke of York of all the territory between Pemaquid and the St. Croix. In 1677 the claims of the Gorges heirs were bought by Massachusetts, and by the charter of 1691 Massachusetts was confirmed in possession of the territory. East of the Penobscot the French held the land and assiduously stirred up the Indian tribes against the English. In 1675 an outbreak of the Tarentine tribe marked the beginning of a long struggle in which most of the towns on the coast east of the Piscataqua were laid waste. The country suffered greatly, too, in the French and Indian wars. During King William's reign the inhabitants of Cocheco were massacred by the Penacook Indians, Pemaquid was taken, and the settlements east of Falmouth were abandoned. From 1722 to 1725 the tribes of Nova Scotia and eastern Maine waged a fierce warfare against the colonists, and security was not really established till the Treaty of Paris in 1763. During the Revolution Maine was active in the patriot cause. At the end of the war Massachusetts retained possession of the territory, exercising jurisdiction over it as the District of Maine. Disputes with the mother State were frequent, and between 1783 and 1791 steps towards independence were taken. The tendency towards separation was hastened by the fact that the inhabitants of Maine were Democratic in their political sympathies and tolerated with difficulty the rule of Federalist Massachusetts. In the War of 1812 Maine was left ill defended by Massachusetts, and its territory east of the Penobscot was occupied by the British. After the war the separatist movement grew rapidly. Probably, however, the desire for separation from Massachusetts would not have been so quickly realized if the struggle over the admission of Missouri into the Union had not brought about the necessity of admitting a Northern State to preserve the balance of power. On March 15, 1820, Maine became a State. Industry and commerce received a great impetus after the War of 1812, but throughout the nineteenth century the increase in wealth and population was rather steady than swift. The dispute with England concerning the northeastern boundary of the State was the cause of constant quarrels between the inhabitants of Maine and New Brunswick. The officials sent out by both to take possession of the disputed lands on the St. Croix River came into collision, and hostilities were prevented only by the signing of the Webster-Ashburton Treaty (q.v.) in 1842. The only important subject of legislation in the State of other than local interest has been that of prohibition. After some tentative lawmaking a stringent prohibitory law, passed in 1858, was incorporated into the constitution in 1884 and has remained in force ever since. Many minor regulations looking towards the effectual execution of the prohibitory law have been passed at frequent intervals, but prohibition on the whole has not turned out entirely successful, and evasions of the law are frequent. Before 1856 Maine was generally Democratic in State elections and only once (1840) voted against the Democratic candidate in presidential elections. From 1856 to 1880 it was emphatically Republican, except in the year 1878, when the Democrats and Greenback party in fusion succeeded in electing their candidate for Governor. The Governor chosen in 1878 was Alonzo Garcelon. In 1879 an election for members of the Legislature took place, and Governor Garcelon, desirous of gaining the Legislature for the fusion party, seized every opportunity afforded by the irregular but time-honored way in which elections were conducted to refuse certificates to Republican candidates and seat Democrats in their place; a Democratic majority was thus secured, and the Legislature was organized. The Republicans organized a rival body and proceeded to elect a Governor, since no candidate had received a majority at the polls. Peace was preserved by the militia until a decision of the Supreme Court established the legality of the Republican Legislature. In 1891 the Australian ballot law was passed. The Legislature in 1907 passed a measure repealing the Sturgis law providing for the strict enforcement of prohibition. This was vetoed by Governor Cobb. The State elections in 1908, held on the issue of prohibition, resulted in a victory for Bert M. Fernald, Republican, who favored the strict enforcement of the law. In 1910, however, the conditions were reversed, when Frederick W. Plaisted, the Democratic candidate, defeated his Republican opponent, thus giving the State to the Democrats for the first time since 1882. Mr. Plaisted and the Legislature were pledged to resubmit to the people the question of prohibition. On March 2, 1911, the Legislature passed a measure submitting the question of repeal of the prohibition amendment to the people. This was followed by the most bitter and aggressive campaign in the history of the State, and on September 11 the amendment was defeated by a vote of 60,853 against 60,095. All the cities in the State, with one exception, voted for the repeal of the law. This ended the effort to bring about the repeal of the prohibition of the State.

Before 1910 Maine was considered a strong Republican State. In the election on Nov. 3, 1908, Taft received 67,120 votes and Bryan 35,880. As noted above, however, the Democrats, largely as a result of local issues, were able in 1910 to elect a Governor and a Legislature. This then enabled the Democrats to elect a United States Senator to succeed Eugene Hale, who was not a candidate for reëlection, and on January 17 Charles F. Johnson was elected. The death of Senator Frye on Aug. 8, 1911, was followed by the appointment of Obadiah Gardner to fill out his unexpired term. This gave the State two Democratic Senators for the first time since the Civil War. In the election of 1911 a direct primary law for all State and county officers and United States Senators was adopted, as was a constitutional amendment making Augusta the permanent capital.

In 1912 the Republicans had so far regained their strength that they were able to elect William T. Haines Governor, defeating Governor Plaisted, who was a candidate for reëlection. In 1912 the State was carried by Wilson, who received 51,113 votes to 48,493 for Roosevelt and 26,545 for Taft. The Legislature elected was composed of a majority of Republican and Progressive votes. The division in the Republican party resulted in the election on Sept. 14, 1914, of Oakley C. Curtis, Democrat, for Governor, defeating William T. Haines, who was a candidate for reëlection.

The following have been Governors of Maine:

William King	Democrat	1820–21
William D. Williamson (acting)	Democrat	1821
Albion K. Parris	Democrat	1822–27
Enoch Lincoln	"	1827–29
Nathan Cutter (acting)	"	1829–30
Jonathan D. Hunton	"	1830–31
Samuel E. Smith	"	1831–34
Robert P. Dunlap	"	1834–38
Edward Kent	Whig	1838–39
John Fairfield	Democrat	1839–40
Edward Kent	Whig	1840–41
John Fairfield	Democrat	1841–43
Edward Kavanagh	"	1843–44
Hugh J. Anderson	"	1844–47
John W. Dana	"	1847–50
John Hubbard	"	1850–53
William G. Crosby	Whig and Free-Soil	1853–55
Anson P. Morrill	Republican	1855–56
Samuel Wells	Democrat	1856–57
Hannibal Hamlin	Republican	1857
Joseph H. Williams (acting)	"	1857–58
Lot M. Morrill	"	1858–60
Israel Washburn	"	1861–63
Abner Coburn	"	1863–64
Samuel Cony	"	1864–67
Joshua L. Chamberlain	"	1867–71
Sidney Perham	"	1871–74
Nelson Dingley	"	1874–76
Selden Connor	"	1876–79
Alonzo Garcelon	Democrat-Greenback	1879–80
Samuel F. Davis	Republican	1880–81
Harris M. Plaisted	Democrat-Greenback	1881–83
Frederick Robie	Republican	1883–87
Joseph R. Bodwell	"	1887
Sebastian S. Marble (acting)	"	1887–89
Edwin C. Burleigh	"	1889–93
Henry B. Cleaves	"	1893–97
Llewellyn Powers	"	1897–1901

John F. Hill	Republican	1901–05
William T. Cobb	"	1905–09
Bert M. Fernald	"	1909–11
Frederick W. Plaisted	Democrat	1911–13
William T. Haines	Republican	1913–15
Oakley C. Curtis	Democrat	1915–17
Carl E. Milliken	Republican	1917–21
Percival P. Baxter	"	1921–

MAINE, Sir Henry James Sumner (1822–88). An English scholar and jurist. He was born Aug. 15, 1822, and in 1840 he went to Pembroke College, Cambridge. After a brilliant career as student he was made tutor in Trinity College in 1845 and in 1847 he was appointed regius professor of civil law in the university. He resigned in 1854 to become reader on jurisprudence in the Middle Temple. In 1862, after repeated invitations, he went to India as law member of the Indian Council. This office he filled with high distinction, his extensive knowledge of primitive peoples enabling him to introduce many important legislative reforms. He remained in India until 1869. On his return to England he was elected professor of jurisprudence at Oxford, and the next year he was made a member of the Council of the Secretary of State for India, receiving the dignity of knighthood. In 1877 he was elected master of Trinity Hall, Cambridge, and in 1878 he resigned his Oxford professorship. In 1887 he became professor of international law at Cambridge. His academic duties did not prevent him from residing in London, where he figured as a successful journalist and as a valued member of the Council for India. He published a number of works embodying his research on the origin and development of institutions, the condition of primitive society, and the growth of law and legal conceptions. On these subjects he is one of the highest authorities. The value of his contributions to science was recognized by various foreign societies which elected him to membership. His chief works are: *Roman Law and Legal Education*, published in the *Cambridge Essays* (1856); *Ancient Law* (London, 1861); *Village Communities in the East and West* (ib., 1871); *Lectures on the Early History of Institutions* (1875); *Modern Theories of Succession to Property* (1878); *Dissertations on Early Law and Customs; Popular Government* (1885). These works are characterized by keenness of judgment, wide learning, and literary finish. He died in 1888. Consult: Frederick Pollock, *Oxford Lectures* (Oxford, 1890), and M. E. Grant-Duff, *Sir Henry Maine: A Brief Memoir of his Life* (London, 1892).

MAINE, University of. A coeducational State institution at Orono, Me., founded on the national land grant in 1865 under the name of the State College of Agriculture and Mechanic Arts. The present name was assumed in 1897. The university comprises the colleges of Arts and Sciences, Agriculture, Technology, and the college of Law at Bangor. The Maine Agricultural Experiment Station is a department of the university. The university confers the bachelor's and master's degrees in arts, philosophy, science, and law; the bachelor's degree in agriculture, engineering, forestry, and home economics; the degrees of chemical, civil, mechanical, and electrical engineer, and pharmaceutical chemist. Military instruction is required by law. Students are admitted upon examination or on a certificate from an accredited school. The total attendance in 1913–14 was 1058, and the faculty numbered 126. The library contained about 40,000 volumes. The endowment was $238,300; the value of grounds and buildings, $588,483; and of all other college property, $230,000. The income was (1913–14) $396,616, of which $30,000 was received from the Federal government for the experiment station and $50,000 was provided by the continuing State appropriations. The college of Arts and Sciences maintains a summer term. The president in 1915 was Robert Judson Aley.

MAINE DE BIRAN, mân de bē′räN′, François Pierre Gonthier (1766–1824). A French metaphysician. He was born at Bergerac in the Department of Dordogne and was trained by the *frères doctrinaires* of Périgueux. In 1785 he joined the bodyguard of Louis XVI, but retired to his native town soon after the outbreak of the Revolution. He was elected to, but not allowed to serve with, the Five Hundred in 1797, became *sous-préfet* of Bergerac in 1806, Count of the Empire in 1809, and in 1812 made his permanent home in Paris. He changed from Napoleon to the Bourbons, sat in the loyal chamber of 1816, and remained an ardent royalist till his death, July 20, 1824. Maine de Biran published very little during his lifetime, and his full importance was appreciated only by those who knew him intimately, men like Royer-Collard and Cousin, the latter of whom speaks of Biran as his teacher. His theories in their entirety remained unknown until Cousin published a second installment of his works in 1841, and Naville issued his *Life* (1851) and an edition of his important writings (1859). Chief among these are: *Nouvelles considérations sur les rapports du physique et du moral de l'homme; Essai sur les fondements de la psychologie; Nouveaux essais d'anthropologie.* In the beginning Biran was a sensualist and a follower of Condillac, but found physiological mechanism incapable of explaining the phenomenon of consciousness. He worked out a system of personality in which the ego was made the centre of the universe, original and uncreated itself, creating everything outside itself. This ego Biran identified with living force—will (in this anticipating Schopenhauer). At first will is merely blind, unconscious effort (like Schopenhauer's will-to-live); passing through the stages of sensation, or glimmering consciousness and perception, or the consciousness of concrete objects, it attains its highest development in reflection, abstract thought, when the ego formulates mathematical truths and is capable of contemplating itself. Life, then, is will; and the outer world is not material, but merely the impression produced by the clashing of other wills against our own. The world exists only as conditioned by will; God exists because the idea of God is necessarily grounded in the nature of the will. If the world, he went on to argue, is the realization of will, does not the unchanging order of the universe presuppose an invincible, infallible will, striving ever at one aim according to immutable laws of its own nature? Such an exalted living force Biran failed to find in the pitiful human will, and he saw himself driven into the assumption of a superhuman will, whose image the universe might be—God. And as formerly everything and God were to him creatures of man's will, now everything, including man, was but the manifestation of the divine will. Consult: J. E. Naville, *Maine de Biran* (3d ed., Paris, 1874); Albert Lang, *Maine de Biran und die neuere Philosophie* (Cologne, 1901); N. E. Truman, *Maine du Biran's Philosophy of Will* (New York, 1904); Marius Couaillhac, *Maine de Biran* (Paris, 1905).

MAINE-ET-LOIRE, â lwär. A northwestern inland department of France, bounded on the west by the Department of Loire-Inférieure and on the east by that of Indre-et-Loire (Map: France, N., E 5). Area, 2787 square miles. It is bisected from west to east by the Loire. It is a gently rolling country with fertile soil, producing cereal and vegetable crops and a variety of excellent fruits. The vine is largely cultivated; stock raising is carried on. Iron and coal mines are worked; there are numerous mills and factories for the production of cotton, woolen, and linen goods; and a good river trade in live stock, cereals, hemp, and cotton passes down the Loire. Capital, Angers. Pop., 1901, 514,658; 1911, 508,149.

MAINE LIQUOR LAW. See MAINE.

MAIN GUARD. The principal guard of a post or camp is called the main guard, to distinguish it from purely local or minor guards, as stable guard, park guard, etc. Where regiments are brigaded together on service or in camp it is the guard pertaining to the camp and brigade headquarters. See GUARD.

MAINLAND, mān′land, or POMONA. The largest of the Orkney Islands (q.v.).

MAINLAND. The largest of the Shetland Islands (q.v.).

MAIN′PRIZE, or **MAIN′PRISE** (OF. *mainprise, meinprise*, surety, bail, from *mainprendre*, to take surety, from *main*, hand, from Lat. *manus*, hand + *prendre*, to take, from Lat. *prendere, prehendere*, to seize, from *præ*, before + *hendere, Gk. χανδάνειν, *chandanein*, to seize; ultimately connected with Eng. *get*). In English law, a proceeding by which a person was temporarily released from prison upon an undertaking being given by one or more responsible persons, known as mainpernors, to produce him at the trial. It is very ancient in its origin and was common in the reign of Edward I. It differed from bail in that the mainpernors had not the custody of the released prisoner and could not surrender him up at discretion as in case of bail. The practice is now obsolete, having been superseded by bail (q.v.).

MAINS, GEORGE PRESTON (1844–). An American Methodist Episcopal clergyman and publisher, born at Newport, N. Y. He served in the United States navy under Admiral Porter in 1864–65; graduated from Wesleyan University in 1870; and entered the ministry, joining the New York East conference of his denomination. Subsequently he filled pastorates in New York, Brooklyn, and Connecticut. He served one year as presiding elder; for a time was superintendent of the Brooklyn Church Society; and was a delegate to every General Conference after 1892. In 1896 he became one of the board of managers of the Methodist Board of Foreign Missions, treasurer of the Episcopal Fund, and one of the publishing agents of the Methodist Book Concern. His writings include: *The Life of Francis Asbury* (1909); *Modern Thought and Traditional Faith* (1911); *Some Moral Reasons for Belief in the Godhead of Jesus Christ* (1912); *Christianity and the New Age* (1914).

MAIN′TENANCE (OF., Fr. *maintenance*, from *maintenir*, to maintain, from Lat. *manu tenere*, to hold in the hand, from *manu*, abl. sing. of *manus*, hand + *tenere*, to hold). In its legal sense, an officious intermeddling by a person in litigation in which he is not concerned or financially interested, by assisting either party with money or otherwise. It includes the offense of champerty, which consists of maintenance for reward or for a share in the proceeds of the litigation promoted. A maintenous agreement is illegal and therefore void, and the offense is punishable as a crime at common law on the theory that it tends to increase groundless and vexatious litigation and to obstruct the administration of justice. The early common law carried the doctrine to extremes, and it was formerly dangerous for a man to advise a friend to consult a lawyer to protect his rights, but it has been greatly modified in the course of time, and to-day where the common law prevails the wrongful intention with which the assistance is given is considered the gist of the offense. Thus, if one assists a relative or a friend to carry on litigation solely because of the relationship existing between them, or if a master assists a servant or any one assists another from motives of charity, he is not guilty of maintenance. At common law a civil action for damages may be brought by the injured party against a maintainor of the suit against him, and such right still exists in many jurisdictions where maintenance as a criminal offense is no longer recognized. In several States it is no longer recognized as a criminal offense and probably not as a civil cause of action. See BARRATRY; CHAMPERTY. Consult the authorities referred to under CRIMINAL LAW; TORT.

MAINTENON, mäɴ′t′-nôɴ′, FRANÇOISE D'AUBIGNÉ, MARQUISE DE (1635–1719). Mistress and second wife of Louis XIV. She was the daughter of Constant d'Aubigné and of Jeanne de Cardillac, and granddaughter of Théodore Agrippa d'Aubigné, the famous Protestant champion. She was born Nov. 27, 1635, in the prison at Niort, where her parents were then incarcerated. On obtaining their release, her parents went to Martinique, where the father died in 1645. After her father's death, Françoise returned to France with her mother, after whose death her father's sisters took her under their care and educated her in a convent, where her conversion to the Roman Catholic religion was accomplished at the age of about 14. When she was 16 she became acquainted with the poet

Scarron (q.v.), who, struck by her beauty, intelligence, and helpless condition, offered her his hand, or, if she should prefer it, a sum of money sufficient for her entrance into a nunnery. Although Scarron was lame and deformed, she chose to marry him, and lived in the midst of the intellectual society which frequented the house of the poet. On his death in 1660 she was reduced to great poverty; but through the intervention of Madame de Montespan (q.v.) obtained a pension from the King. In 1669 she was intrusted with the education of the two sons whom Madame de Montespan had borne to Louis XIV, and in this capacity attracted the attention of the King by her excellent intellectual gifts, finally supplanting Madame de Montespan in the changeable monarch's regard. War between the two women resulted in the triumph of the new favorite. The King bestowed on her the sum of 100,000 livres, with which she bought the estate of Maintenon and in 1675 received the title of marquise, and from that time to the end of his life she exercised an extraordinary ascendancy over him. She had become an ardent Catholic and exerted a powerful religious influence over the King, and although keeping herself in the background was able to direct foreign policy and internal affairs in the interests of clericalism. She favored the Revocation of the Edict of Nantes, but was opposed to the violent persecutions that followed it. Louis privately married her in 1684, soon after the death of the Queen, and, though she was never publicly acknowledged as his wife, her position at court was quite different from that of her predecessors in the favor of the King. She carefully brought up the children of Madame de Montespan; and it was at her instigation that Louis legitimatized them. When he died in 1715 she retired to the former abbey of St. Cyr, which, at her wish, had been changed 30 years before into a convent for young ladies. Here she died, April 15, 1719.

Bibliography. P. Noailles, *Histoire de Mme. de Maintenon* (4 vols., Paris, 1848–58); T. S. Lavallée, *Madame de Maintenon et la maison royale de St. Cyr* (ib., 1876); John Lord, *Beacon Lights of History*, vol. v (New York, 1884); M. A. Geoffroy, *Mme. de Maintenon d'après sa correspondance authentique* (Paris, 1887); Ferdinand Brunetière, "Mme. de Maintenon," in *Revue des Deux Mondes* (ib., 1887); A. de Boislisle, *Paul Scarron et Françoise d'Aubigné d'après des documents nouveaux* (ib., 1894); A. Rosset, *Mme. de Maintenon et la révocation de l'edict de Nantes* (ib., 1897); Chabaud, *Les précurseurs du féminisme: Mme. de Maintenon, De Genlis, et Campan* (ib., 1901); Mdlle. d'Aumale, *Souvenirs de Mme. de Maintenon*, published by Comte d'Haussonville and G. Hanotaux (3 vols., ib., 1902–04); E. Pilastre, *Vie et caractère de Mme. de Maintenon* (ib., 1907); C. C. Dyson, *Madame de Maintenon: Her Life and Times, 1635–1719* (London, 1910); C. J. Blennerhassett, *Louis XIV and Madam de Maintenon* (New York, 1911). The correspondence of Mme. de Maintenon (so far as she did not destroy it as in the case of her correspondence with Louis XIV) has been published by T. S. Lavallée, *Lettres historiques et édifiantes* (Paris, 1854–66) and *Correspondance générale* (ib., 1888). The latter contains, however, many forged letters. Consult P. Grimblot, *Faux autographes de Mme. de Maintenon* (Paris, 1867).

MAINZ, mīnts (Fr. *Mayence*). The largest town in the Grand Duchy of Hesse, and one of the most ancient cities of Germany and a great fortress of the Empire (Map: Germany, C 4). It is situated on the left bank of the Rhine almost opposite the influx of the Main, about 18 miles northwest of Darmstadt. The southern and older part of the city, with its narrow and irregular streets and Gothic buildings, presents a striking contrast to the modern quarters in the north, built up since the reconstruction of the fortifications. A fine modern bridge of five arches crosses the Rhine, whose width here is the greatest of its upper course, to Kastel. During the three years prior to 1910 Kastel and other suburbs were annexed to Mainz. A handsome esplanade extends along the left bank of the river.

In the centre of the old town stands the cathedral, imposing in appearance and showing in its numerous additions and alterations traces of an eventful existence. It was constructed in 978–1008, but the present building dates principally from the thirteenth century, the original structure having been destroyed by several conflagrations. It is Romanesque with Gothic additions and details, and is surmounted by six towers, of which the highest rises to 270 feet. Noteworthy features are the tenth-century brazen doors of the main entrance and the tombs of Boniface, the first Archbishop of Mainz, of Frauenlob the Minnesinger, and of numerous archiepiscopal electors. The cathedral was restored in 1856–79. Mainz has several other Roman Catholic churches, the most notable of which are those of St. Stephen, St. Ignatius, and St. Peter. The church of St. Stephen (1257–1328), with interesting cloisters, has a sightly situation above the Rhine; that of St. Ignatius has a finely painted ceiling. On the Gutenberg-Platz, near the cathedral, stands a Thorvaldsen monument (1837) to Gutenberg, a native of Mainz.

Facing the Schloss-Platz is the former electoral palace (1627–78), now used as a museum. It is a red sandstone building of large proportions. It contains one of the most extensive collections of Roman and Germanic antiquities in Germany, the municipal library of 230,000 volumes (1913) and numerous manuscripts, a rather unimportant picture gallery, and the Gutenberg Museum, founded in 1901. The former lodge of the Teutonic Order (1731–39) is now used as the grand-ducal residence. Mainz has also a number of fine modern buildings, notably the city hall, the theatre, and the central railway station.

The fortifications, enlarged since 1871, consist of several lines of bastioned forts, the citadel in the southeastern part of the town, and a number of detached forts. Kastel, on the opposite side of the Rhine, forms the *tête de pont*. There are numerous Roman remains in the town and the vicinity, including parts of an aqueduct and what is supposed to be a monument to Drusus. The chief educational institutions comprise two Gymnasia, a seminary for priests, a school of commerce, and a number of other special schools. The university founded in 1477 was suppressed in 1798.

Mainz is well known for its leather goods and furniture, and it manufactures also musical instruments, carriages, carpets, and chemicals. Book and art publishing is also carried on extensively. Mainz is well adapted for commerce by its position at the confluence of two important waterways; but the competition of other

Rhine ports has detracted somewhat from its prominence in trade. The city is still, however, an important factor in the Rhine traffic with the Netherlands and Belgium. Pop., 1890, 72,059; 1900, 84,251; 1905, 91,179 (largely Roman Catholics, the number of Evangelicals being 34,607 and of Jews 3058); 1910, 110,634 (including districts annexed in 1912, 118,107).

The site of Mainz was occupied in ancient times by a Celtic settlement, which was later converted into a Roman camp. Drusus erected here in 13 B.C. a castle called Maguntiacum, and the settlement was connected by a bridge with the Castellum Mattiacorum (Kastel) on the opposite shore. With the dissolution of the Roman Empire Mainz was repeatedly pillaged by the Allemanni, the Vandals, and the Huns, but it gradually recovered, and by the tenth century was regarded as an important city. It obtained privileges from Charlemagne and headed the league of Rhenish towns in the thirteenth century. In the fifteenth century Mainz acquired great celebrity on account of Gutenberg, and became the centre of early book printing.

The decline of the city began in the second half of the fifteenth century, when it was deprived of its Imperial privileges for its support of the Archbishop Diether von Isenburg and became an archiepiscopal city. Mainz was occupied by the Swedes in 1631 and by the French in 1644 and 1688. In 1792 the city, deserted by the Prince-Elector and the court, capitulated to the French under General Custine, was retaken in the following year, and formally ceded to France by the Peace of Lunéville in 1801. It was returned to Germany by the Peace of Paris in 1814, and was annexed to the Grand Duchy of Hesse in 1816, remaining, however, a fortress of the German Confederation.

The archbishopric of Mainz was founded in 747 with St. Boniface as its first Archbishop. The archbishops of Mainz were preëminent among the spiritual electors of the Empire. The archbishopric was degraded to a bishopric in 1801, and the see was secularized in 1803. Consult K. Hegel (ed.), *Die Chroniken der mittelrheinischen Städte: Mainz* (2 vols., Leipzig, 1881–82).

MAIOLICA, mȧ-yŏl′ĭ-kȧ. See MAJOLICA.

MAIPO, mī′pō, or **MAIPU**, mī′po͞o. A river of Chile, rising in the Andes and flowing westward 120 miles into the Pacific Ocean. It passes a few miles south of the city of Santiago. On its banks was fought on April 5, 1818, the decisive battle which secured the independence of Chile.

MAIPURE, mī-po͞o′rȧ. A prominent and populous group of tribes of Arawakan stock (q.v.), formerly dwelling on the Ventuari River, an upper affluent of the Orinoco, in southern Venezuela. Two centuries ago they were one of the leading mission tribes of the Orinoco region, but, like many others, gradually wasted away before the incessant inroads of the Caribs, who were accustomed to make periodical expeditions up the river in fleets sometimes of a hundred canoes, destroying every village along its banks.

MAIR, mâr, CHARLES (1840–). A Canadian poet and journalist of Scottish descent, born at Lanark, Ontario. He was educated at Queen's University, Kingston, afterward studied medicine, and was for some time engaged in business, in the meantime contributing both in prose and verse to leading periodicals. He went to the Canadian Northwest and became the Fort Garry (now Winnipeg) correspondent of the Montreal *Gazette*. During the first rebellion (1869) of Louis Riel (q.v.) he was imprisoned and condemned to death; but he escaped and served as a government medical officer during Riel's second rebellion (1885). After living on a ranch in British Columbia for some years he returned to Saskatchewan, and later entered the civil service at Lethbridge, Alberta. He was one of the founders of the Canada First party (1870). In 1889 he was elected a fellow of the Royal Society of Canada. He published: *Dreamland and Other Poems* (1868); *Tecumseh: A Drama* (1886); *The Last Bison* (1888); *Through the Mackenzie Basin* (1908).

MAIR, JOHN. See MAJOR, JOHN.

MAIRET, mȧ′rȧ′, JEAN DE (1604–86). A French dramatic poet, born at Besançon. His earlier dramas include: *Silvanire* (1625); *Les galanteries du duc d'Ossone* (1627), a comedy modeled on the Italian order; *Sophonisbe* (1629), the first of French classical tragedies to be given on the regular stage. His other works are of little importance. He became involved in the quarrel that followed the presentation of the *Cid* (1637), and Mairet and Scudéry were Corneille's bitterest opponents.

MAISCH, māsh, JOHN MICHAEL (1831–93). An American pharmacist, born in Hanau, Germany. He was educated in his native town and came to the United States in 1849. In 1861–63 he was professor of materia medica in the New York College of Pharmacy, and from 1866 until his death professor of materia medica and botany at the Philadelphia College of Pharmacy. He was editor of the *American Journal of Pharmacy* from 1871 to 1893; assisted in the preparation of *Griffith's Universal Formula* (3d ed., 1874); with Stillé edited the *National Dispensatory* (4th ed., 1879–86); and published *A Manual of Organic Materia Medica* (1881; 7th ed., 1899).

MAISON, mȧ′zôɴ′, NICOLAS JOSEPH (1770–1840). A French marshal, born at Epinay (Seine). He entered the army in 1792 and seven years later was adjutant general under Bernadotte. He distinguished himself at Austerlitz in 1805 and was prominent in the campaigns that followed that battle, but did not attain the rank of general of division until 1812 after the battle of Polotsk. In 1813 he was at the head of the Army of the North and maintained a sturdy resistance against the allies. After Napoleon's abdication he attached himself to the government of Louis XVIII, was made a peer, appointed Governor of Paris in 1815, and became a marquis in 1817. During the expedition to Morea in 1828–29, which he commanded, he received the baton of marshal. He was for a short time Minister of Foreign Affairs in 1830, and afterward Ambassador to Vienna (1831), to St. Petersburg (1833), and Minister of War (1835–36).

MAISON CARRÉE, mȧ′zôɴ′ kȧ′rȧ′. A beautiful and well-preserved Roman temple at Nîmes, France, dating probably from the early years of the Christian era, though some authorities have placed it as late as the second century A.D. The building is of Corinthian architecture and measures 45 by 85 feet. It stands on a platform approached by 15 steps. It is surrounded by 30 columns of which six form the façade and 20 are engaged in the walls of the cella. After serving as a church and for other uses it is now used as a museum.

MAISON DORÉE, dô′râ′ (Fr., gilded house). A famous Parisian restaurant on the Boulevard des Italiens, built in 1839. When in recent years the former extravagance in dining passed away, such establishments ceased to be profitable, and in 1903 the Maison Dorée was compelled to close its doors.

MAISON DU ROI, dụ rwä (Fr., house of the King). A title applied during the monarchical régime in France to a select corps of troops, including the Gardes du Corps, Chevauxlégers, Mousquetaires, Grenadiers à Cheval, the French and Swiss Guards, and the Cent Suisses. During the reign of Louis XIV they were entirely separate from the regular army establishment. They corresponded to the present Household Troops (q.v.) of England.

MAISONNEUVE, mâ′zô′nēv′. A city within the territorial limits of the city of Montreal, Canada. Among its notable buildings and institutions are the city hall, public market, post office, public bath and gymnasium, and the dry dock and navy yard. There are about 45 industries employing about 18,000 hands, and the chief manufactures include sugar, cotton and cotton goods, thread, foundry and machine-shop products, boots and shoes. In 1910 the manufactured output, which ranked as sixth in Canada, was valued at $20,813,774, as compared with $6,008,780 in 1900. The city is abundantly supplied with water and electric power for manufacturing purposes. Pop., 1901, 3958; 1911, 18,684; 1915 (local est.), 36,500.

MAISONNEUVE, Paul de Chomedey, Sieur de (?–1676). A French colonial Governor in Canada and founder of Montreal. He was born in Champagne. He early entered the French army and served in many campaigns in Holland. He became interested in the attempt to found a religious colony in New France by the body afterward known as the Associates of Montreal, and in 1641 with 40 men and four women reached Quebec. The next year, on May 18, he founded the city of Montreal, of which he was Governor for 22 years. Troubles came fast, and all his wisdom and firmness were necessary to keep the colony on its feet. The patrons had no conception of its economic needs, as they were moved entirely by religious enthusiasm. He was continued as Governor after the colony came under Sulpician auspices, though much harassed by the government at Quebec, which resented the virtual independence of Montreal. On this account he was removed by De Tracy in 1665 and sent to France, where he died in obscurity. He was a brave, disinterested man, who gave all his energies to the service of the colony.

MAISTRE, mâ′tr′, Joseph, Count de (1754–1821). A French philosopher and political writer and statesman in the service of Sardinia, born in Chambéry of a noble French family that had settled in Savoy when it belonged to the Sardinian Kingdom. Driven from his native country by the invasion of the French (1792), De Maistre, who was a member of the Senate, escaped first to Lausanne and then to Turin, and when, in 1798, the King was compelled to abandon his continental possessions, De Maistre accompanied the court to the island of Sardinia. From 1803 to 1817 he represented his impoverished King at St. Petersburg, and upon his return was appointed Minister of State and Regent of the Grand Chancery. It was during this long period of comparative peace that most of his literary work was done. De Maistre was an ardent advocate of legitimacy, and in his later career became one of the most eminent writers of the new (or liberal) conservative school in politics and religion, of which Chateaubriand may be regarded as the head. His first work of note was *Considérations sur la France* (1796), in which he combated the revolutionary doctrines then in vogue. His later works include: *Essai sur le principe générateur des constitutions politiques* (1810), advocating an absolute monarchy; *Du pape* (1819; new ed., 1891), probably the best modern defense of the spiritual and temporal power of the Pope; *De l'église gallicane* (1821–22). His *Les soirées de Saint Petersbourg* (1821; new ed., 1888), *Examen de la philosophie de Bacon* (1836), *Lettres et opuscules inédits du comte Joseph de Maistre* (1851), and *Mémoires politiques et correspondance diplomatique* appeared posthumously. *Quatre chapitres inédits sur la Russie par le comte Joseph de Maistre* (1859) was published by his son Rodolphe. There are also editions of his *Œuvres complètes* (1864) and *Œuvres posthumes* (1864).

Bibliography. Margerie, *Le comte Joseph de Maistre* (Paris, 1890); Lescure, *Le comte Joseph de Maistre et sa famille* (ib., 1893); Descostes, *Joseph de Maistre avant la révolution* (ib., 1893); id., *Joseph de Maistre pendant la révolution* (ib., 1895); Mandoul, *Maistre et la politique de la maison de Savoie* (ib., 1900); Descote, *Joseph de Maistre inconnu* (ib., 1904).

MAISTRE, Xavier de (1763–1852). A French essayist and novelist, brother of Joseph de Maistre (q.v.). Having been in the military service of Sardinia, on its conquest by the French he emigrated to Russia (1799), where he became major general and took part in the Persian campaign, gathering there materials for his most famous story, *Les prisonniers du Caucase* (1825). His first book, *Voyage autour de ma chambre* (1794), was written in the style of Laurence Sterne, in Turin, while De Maistre was under arrest for participation in a duel. The *Expédition nocturne autour de ma chambre* (1825), in like style, was less successful. He wrote also two stories, *Les lépreux de la cité d'Aoste* (1811) and *Prascovie, ou la jeune Sibérienne* (1825), imitated from Madame Cottin's once noted *Les exilés de Sibérie* (1806). His essays are a genial afterglow of eighteenth-century wit, and his stories are models of vigorous and direct narration, combining power of exact description with sentimental affectation in a way that puts him quite apart among the French novelists.

MAISUR, mī-sōōr′. See Mysore.

MAITLAND, māt′land. A town of New South Wales, Australia, in Northumberland County, on the Hunter River, 119 miles by rail north of Sydney and 15 miles by rail northwest of Newcastle (Map: New South Wales, F 3). It is divided by the river into East and West Maitland, two distinct municipalities. In either division are handsome banks, churches, and other public buildings. In West Maitland, the more populous part, are several coach-building factories, tobacco factories, and several mills, including a paper mill. Good coal is mined in the neighborhood. The district is called the "garden of New South Wales," and an extensive trade is carried on in agricultural produce. The Maitland coal field is one of the greatest and finest in the world, a great district being underlain by huge seams of pure coal, up to 33 feet in thickness, worked by splendid plants. Total population of East and West Maitland, 1903, 10,340; 1911, 11,313.

MAITLAND. The family name of the earls and dukes of Lauderdale (q.v.).

MAITLAND, Edward (1824–97). An English mystical and humanitarian writer, born at Ipswich. After graduation from Caius College, Cambridge (B.A., 1847), a sojourn in California in 1849, and experience as Commissioner of Crownlands in Australia, he settled down in London to his life work as a writer (1857). Many of the vicissitudes of his inner and outer life are reflected in his romance, *The Pilgrim and the Shrine* (1867), which was followed by *The Higher Law* (1869), in which the hero presents himself as rising superior to traditional morals. By this time Maitland had become a figure in society and in letters. In 1873 he made the acquaintance of (Mrs.) Anna Kingsford, with whom he and his work were closely associated until her death (1888). Meantime he and she collaborated in *The Keys of the Creeds* (1875) and in *The Perfect Way, or the Finding of Christ* (1882); and with one accord they opposed themselves to orthodoxy, animal food, materialism, and vivisection. In 1884 he and Mrs. Kingsford withdrew from the Theosophical Society, which they had joined in 1883, and founded the Hermetic Society, and Maitland became more and more the mystagogue, and at last became apparently somewhat unbalanced and distraught. He claimed a special sense by which he could discern the spiritual condition of others and could see the souls of trees and men; and he recalled incidents of his previous incarnations as an ancient Theban, Marcus Aurelius, St. John the Evangelist, etc. In later life his chief aim was to live up to his motto "An honest God's the noblest work of man," and for the creation of a deity after his own heart he labored ceaselessly, leaning the while upon Oriental and Occidental mystics and transcendentalists of the past and the present. Of his later works must be mentioned: *Clothed with the Sun: Being the Book of the Illuminations of Anna (Bonus) Kingsford* (1889); *The New Gospel of Interpretation* (1892); *Anna Kingsford: Her Life, etc.*, which he regarded as his *magnum opus*. His writings, especially *Anna Kingsford*, abound in autobiographical data.

MAITLAND, Frederick William (1850–1906). An English legal scholar and historian. He was educated at Eton and at Trinity College, Cambridge (B.A., 1873; M.A., 1876). In 1884 he became reader in English law at Cambridge, and in 1888 Downing professor. His writings, almost entirely on the early legal institutions of England, have exerted a great influence in this field upon English and American students. His greatest work is the *History of English Law*, the first edition of which appeared in 1895. In this he was assisted by Sir F. Pollock. The work extends to 1307 and cleared up a great number of problems, as did also his series of essays known as *Domesday Book and Beyond* (1897). Another interesting work of Maitland is *Roman Canon Law in the Church of England* (1898), a collection of essays, in which he undertakes to refute the claims of the High Church party, who maintain that the canon law of Rome was never binding on the ecclesiastical courts of England. Free from all pedantry, the very manner and style of Maitland's writings lend surprising interest to topics which the layman might expect to find dry and repellent. His works belong to English letters as well as to English law. His *Life of Leslie Stephen* (1906) is a biography of remarkable charm. Maitland received honorary degrees from Oxford, Cambridge, Glasgow, Cracow, and Moscow, besides many other marks of distinction. Other works of his are: *Gloucester Pleas* (1884); *Justice and Police* (1885); *Bracton's Note-Book* (1887); *Township and Borough* (1898).

MAITLAND, John Alexander Fuller. See Fuller-Maitland, John Alexander.

MAITLAND, Sir Peregrine (1777–1854). A British general and colonial administrator, born at Longparish House, Hampshire. In 1814 he was made a major general and in 1815 took part in the Waterloo campaign. He was Lieutenant Governor of Upper Canada in 1818–28, but his inexperience in civil government led him to rely too much upon his councilors, while his want of tact and autocratic Toryism rendered him unpopular with the mass of the Canadians. The only important event of his administration was the beginning of the Welland Canal. After leaving Canada he was Lieutenant Governor of Nova Scotia from 1828 to 1834, though he spent but one of those years at his post. In 1830 he was promoted lieutenant general; he was commander of the Madras army in 1836–38 and Governor and commander in chief at the Cape of Good Hope in 1844–47. He was knighted in 1852.

MAITLAND, Sir Richard, Lord Lethington (1496–1586). A Scottish lawyer and antiquary of an Anglo-Norman family long settled in Berwickshire. His father, Sir William Maitland of Lethington, was killed at Flodden. Richard Maitland was educated at the University of St. Andrews and studied law in Paris. Returning to Scotland, he was nominated heir to his father and entered the service of James V. During the troubled years that followed the death of the King he aimed at an independent course. As a commissioner in settling disputes on the borders he became famous. On Queen Mary's return from France in 1561 he became an ordinary Lord of Session and a member of the Privy Council, and the next year he was appointed Keeper of the Great Seal. Though totally blind, he held the seal till 1567, and his position on the bench till 1584. He died March 20, 1586. Maitland is remembered mainly for his valuable collection of early poems, in two volumes, now preserved at Magdalene College, Cambridge. Selections from it were published by John Pinkerton under the title, *Ancient Scottish Poems never before Published* (1786). Maitland's own poems, which possess considerable interest, were published with a memoir in 1830 by the Maitland Club, a society founded at Glasgow in 1828 for printing ancient Scottish manuscripts. Some of them were reprinted in the collection entitled *Scottish Poetry of the sixteenth-century* (1892). His *History of the House of Seytoun*, with the continuation by Viscount Kingston, was published by Fullerton (Glasgow, 1829).

MAITLAND, Samuel Roffey (1792–1866). A Church of England scholar. He was born in London and studied at Trinity College, Cambridge, without graduation, as he was not a member of the Church of England. He studied law and was admitted to the bar in 1816, then studied theology and was ordained in the Church of England in 1821. He held perpetual curacy of Christ Church, Gloucester, 1823–29, but resigned to devote himself to literature. In 1838 he was appointed librarian to Dr. Howley, Archbishop of Canterbury, and keeper of the Lambeth manuscripts, retaining the office until the death of the Archbishop, in 1848. From 1839 to 1849 he edited the *British Magazine,* in which he wrote valuable articles, chiefly on prophecy, Church history, criticism, etc. His principal historical works are: *An Inquiry into the Grounds on Which the Prophetic Period of Daniel and Saint John has been Supposed to Consist of 1260 Years* (London, 1826); *Facts and Documents Illustrative of the Doctrines and Rites of the Ancient Albigenses and Waldenses* (1832); *The Voluntary System* (1834); *The Dark Ages: A Series of Essays Intended to Illustrate the State of Religion and Literature in the Ninth, Tenth, Eleventh, and Twelfth Centuries* (1844); *Essays on Subjects Connected with the Reformation in England* (1849); *Superstition and Science* (1855). He wrote also numerous pamphlets, letters, and reviews. He was an omnivorous reader and a man of broad sympathies.

MAITLAND, William (?1528–73). A Scottish statesman, better known as "Secretary Lethington." He was the eldest son of Sir Richard Maitland (q.v.), of Lethington. He was educated at St. Andrews and on the Continent and quickly displayed great aptitude for a political career. He became a convert to the Reformed doctrines about 1555, but could not have been a violent partisan, since in 1558 he was appointed Secretary of State by Mary of Guise. In the following year, however, he openly joined the Lords of the Congregation and was one of the Scottish commissioners who met the Duke of Norfolk at Berwick to arrange the conditions on which Queen Elizabeth would give them assistance. In 1561, after the arrival of Queen Mary from France, he was made an extraordinary Lord of Session. He strongly objected to the ratification of Knox's *Book of Discipline* and in 1563 conducted the prosecution raised against Knox for treason; from this time he appears to have split with the Reformers. In 1564 he held a long debate with Knox on the claims of the Reformed church to be independent of the state. In 1566 he took part in the plot against Rizzio, after whose assassination he was proscribed and obliged to seek shelter for some months in obscurity. He was cognizant of Bothwell's scheme for the murder of Darnley; yet when he saw the hopeless nature of Bothwell's designs he immediately joined the confederacy of the lords. While Mary was still a prisoner at Lochleven he is said to have written to her offering his services, yet he was present at the coronation of King James VI, 1567; and although he secretly aided in the escape of the Queen, he fought against her on the field of Langside. In 1568 he accompanied the regent Murray to the conferences held at York regarding the Scottish Queen; but even here he tried to further her interests, and is said to have been the first to propose to the Duke of Norfolk a union between him and Mary. The Scottish lords felt that he was a dangerous enemy to the commonwealth, and in 1569 he was arrested at Stirling for complicity in Darnley's murder, but was liberated shortly after by an artifice of Kirkaldy of Grange. After the murder of the regent Murray he and Kirkaldy became the leaders of the Queen's party, in consequence of which he was declared a rebel, deprived of his offices and lands by the regent Morton, and besieged, along with Kirkaldy, in Edinburgh Castle. After a long resistance the castle surrendered, and Maitland was imprisoned in Leith, where he died (1573). Buchanan drew his character with a severe pen in *The Chameleon.* In a more charitable estimate he appears as one of the most substantial men of his time, as placing the welfare of Scotland above the bigotry of both Catholics and Protestants, and as governed throughout his career principally by a desire for the union of the crowns of England and Scotland. Consult: George Chalmers, *Life of Mary, Queen of Scots* (3 vols., London, 1822); Sir John Skelton, *Maitland of Lethington* (ib., 1887–88); Andrew Lang, *A History of Scotland* (Edinburgh, 1904–1907); E. Russell, *Maitland of Lethington: A Study of his Life and Times* (London, 1912).

MAÎTRE D'ARMES, mȧ′tr′ därm (Fr., master of arms). A fencing master. In the French army a maître d'armes is assigned to each regiment. In the United States army there is one master of the sword, with the pay of captain, who is on duty at the United States Military Academy as instructor in fencing, military gymnastics, and physical culture. See Fencing.

MAÎTRE DE FORGES, de fôrzh, Le (The Iron Founder). A romance by Georges Ohnet (1882). It was dramatized by the author and presented at the Paris Gymnase in 1883.

MAITREYA, mī-trā′yȧ. A proper name derived from Sanskrit *mitra,* friend, and designating in its Pali from *Metteyya,* the future Buddha, the Buddha of Friendship, who will appear 5000 years after Gautama. At present he is believed to be in the Tushita Heaven of the Blest. He is known in Tibet as Jampa (Tib. *Byams-pa,* pronounced Jam-pa or Champa) and is believed to be of gigantic size, so that colossal statues are used to represent him. The worship of Maitreya overshadowed that of Buddha in the Hosso sect, which flourished in Japan in the eighth century of our era. Consult: Schlagintweit, *Buddhism in Thibet* (London, 1868); Waddell, *The Buddhism of Tibet* (ib., 1895); Rhys Davids, *Buddhism* (ib., 1900).

MAIZE (Sp. *maíz,* from Haïtian *mahiz, mahis,* the native name), or Indian Corn (*Zea mays*). An annual grass with erect stems and spreading leaves; male or staminate flowers borne upon the summit of the stem, which is commonly designated the tassel; and the female flowers upon the ear, which rises from the axils of the leaves. The protruding styles of the female flowers are called the silk, and the united pistillate spikes the cob. Fertilization of the pistillate flowers is accomplished by the wind or other agencies, which carry pollen from the staminate flowers to the silk. The botanical relationship of maize is shown in the discussion of grasses. Its nearest relative is probably the Mexican teosinte (*Euchlæna luxurians*), a plant of the same general habit of growth. Experiments conducted by Harshberger and others have seemed to show that the wild form (which is unknown), or the plant from which maize was derived, is teosinte. Maize differs from most grasses in having solid instead of hollow stems. Adventitious roots are often developed from the nodes near the ground, which serve to brace the plant against winds. The plant varies in height from less than 2 feet in dwarf varieties to more than 30 feet, reported for some forms in the West Indies. Specimens more than 20 feet tall are not infrequent in the rich river valleys in the United States. The size of the ear and size, color, and hardness of the grain show marked variation. Ears vary in length from an inch in varieties of popcorn to 15 inches or more in the dent varieties. White, black, yellow, and red, with numerous variants, are the colors of the grain. In some the grain is no larger than rice grains; in a South American variety, cuzco, the individual grains often weigh 35 times as much as the small popcorn grains. All degrees of hardness are shown, ranging from the flint varieties (so called from their extreme hardness) to the squaw corn and flour corn, the grains of which are so starchy and soft as to be readily broken between the fingers. The season required for maturing varies from one month in a Paraguayan variety to seven months in others. Maize shows a remarkable tendency to mix, as the blending of varieties is called, the pollen of one variety showing its effect upon the grain of another. This may be seen in the common occurrence of variegated grains and in the deterioration of sweet corn and popcorn when planted near field varieties. Abnormal forms are of frequent occurrence, as cobs with staminate flowers upon their extremities, small ears borne towards the bases of tassels, branched and flattened ears, etc.

Although the widespread cultivation of maize has given rise to very many varieties commonly grouped according to certain characters of the grain, most botanists recognize only a single species, *Zea mays*, of very variable habit. Sturtevant, however, has given to the different groups the following specific names: *Zea tunicata*, pod corns; *Zea everta*, popcorns; *Zea indurata*, flint corns; *Zea indentata*, dent corns; *Zea amylacea*, soft corns; *Zea saccharata*, sweet corns; and *Zea amyleasaccharata*, starchy sweet corns. The first group, *Zea tunicata*, or podded corn, which has a pod or husk for each kernel in addition to the enveloping ear leaves, is considered to be the original form of corn; *Zea everta*, or popcorn, its nearest relative; and *Zea amylacea*, or soft corn, the highest developed form. Milo maize, Jerusalem corn, Kafir corn, Egyptian corn, etc., are not varieties of *Zea mays*, but of *Andropogon*, and are known as nonsaccharine sorghums.

Corn is generally thought to be a native of America, probably grown in a wild state on the plateaus of tropical America. All evidence points to its cultivation by the native tribes long before the discovery of the country by Columbus, who is said to have carried the first grains of corn to Europe on his first return voyage. Its cultivation in Europe spread very slowly. Although introduced into Spain at the end of the fifteenth century, it did not reach France until 100 years later. Historical data concerning its distribution in Europe are conflicting in many instances, but modern agricultural writers, summing up the evidence at hand, believe it was introduced into France and Italy from Spain, into Switzerland and Hungary from Italy, into Austria and southeastern Europe from Hungary, and from Switzerland into the valley of the Rhine. It is said to have been carried to Asia and Africa from Portugal. The distribution of maize on the American continents has been coincident with the progress of the white race in the New World. The limits of the distribution of corn culture are given by De Candolle as 40° S. lat. in South America, 54° N. lat. in North America, and 50° N. lat. in Europe. The popcorn (see below), flint-corn, dent-corn, and sweet-corn groups are represented in the United States by many varieties, the dent corn representing the bulk of the corn produced. In Europe and parts of South America the flint corns are more widely distributed than any other group. Flint corn in numerous varieties has a large, hard kernel, either white, yellow, orange, red, blue, striped, or blazed. The ears are usually from 6 to 12 inches long, and the plants commonly grow from 4 to 8 feet high. Dent corn is characterized by the indentation at the top of the kernel, caused by the drying and shrinking of the starchy matter within. The outer portion of the kernel is corneous, as in the pop and flint corns, but the proportion of starch is greater in this group than in either of the other two. The length of the ear usually varies from 6 to 12 inches, and the height of the plant ordinarily from 6 to 10 feet. Most varieties have white or yellow kernels, but various other colors are represented among the many different sorts. The varieties of dent corn exceed in number those of all the other groups combined.

Corn is a universal crop in the United States and is grown on many different kinds of soil, but for its best growth a well-drained, rich, sandy loam, which does not bake during drought, is required. In preparing the soil for corn it is plowed deeper than for any other cereal crop, the object being to obtain a deep and well-pulverized seed bed. In the northern portion of the Mississippi valley, where the bulk of the world's corn crop is produced and where it matures in about five months, it is planted from about the first of May to the twentieth. In other latitudes planting is done late enough to escape late spring frosts. It is most commonly sown in hills or in drills by means of a corn planter, but it is sometimes also sown broadcast. The hills are about 3½ feet apart each way, and three or four stalks are produced per hill; but when planted in drills, single plants are grown about one foot apart in the row. From the time of planting until the young plants appear above ground the soil is harrowed for the purpose of keeping the surface in a pulverized condition and preventing the growth of weeds. The plants are cultivated with the horse hoe or corn cultivator after they have attained sufficient height and until they are too large to admit of further cultivation without injury to the plants. In the principal corn-producing States of the United States cultivation usually commences about the first of June and lasts for about six weeks. Where corn is grown in hills, or checks, the direction of each cultivation after the first is at right angles to the preceding direction, so that the whole of the surface soil may be stirred. Planted in drills it can be cultivated in one direction only.

The practice of listing corn consists in making alternate ridges and furrows by means of the lister, an implement which ridges the soil and drills the corn into the bottom of the furrows at the same time. No previous plowing is generally given. In cultivating listed corn the soil is thrown from the ridges towards the growing plants, so that by the time cultivation is finished the surface of the land has become level. The practice of listing is not general.

The time of harvesting depends somewhat on the use to be made of the crop. When grown for silage or for fodder, corn is cut when the kernels begin to glaze and the lower leaves begin to dry. For silage the cut stalks are immediately passed through the silage cutter into the silo, and for fodder they are put up in shocks and left to cure in the field. When dry the ears are removed and the stalks (fodder or stover) are used directly for feeding purposes or shredded and then fed. Shredding consists in passing the stalks and leaves through a machine which cuts and tears them in fine pieces. A machine known as the shredder and husker removes the ears and shreds the stalks and leaves. Corn grown for the grain is harvested when it is fully ripe and dry. The ears are gathered, husked, and stored in slat cribs, through which the air passes freely, thus drying the corn and preventing attacks of mold. This method of harvesting corn, for which machines have also been perfected, is known as husking, picking, or shucking, the first being perhaps the most common. The term "snapping" corn refers to gathering the ears with most of the husks attached, which is sometimes done when ripe corn is fed directly from the field. Before it is fed or sold corn is usually shelled by passing the huskless ears through hand or power corn shellers.

The most common disease to which corn is subject is smut (q.v.), against which methods of prevention are not well understood. Rust does no material injury to corn. The bacterial disease of corn sometimes does considerable damage. The principal insect enemy is the cutworm, which destroys the young plants. Extensive injury is frequently done by ground squirrels, which feed on the planted seed. These animals are usually poisoned about planting time with poisoned corn and pumpkin seeds. See CORN INSECTS.

The maize crop of the world is estimated at from 3500 to 4500 million bushels annually. The annual corn production of the United States amounts to nearly 3000 million bushels. The great corn-producing States are Illinois, Iowa, Kansas, Nebraska, Missouri, and Indiana. In 1912 these States produced 1,658,450,000 bushels, or more than one-half of the entire crop of the United States. About 50 bushels per acre are considered a good yield, but the average yield per acre for the whole United States is only about 27 bushels. The largest yield of corn on record, 237 bushels per acre, was produced in South Carolina.

Although the United States produces approximately three-fourths of the corn of the world, it exports comparatively little and has in recent years become an importer of corn, the importation of corn in the fiscal year 1914 having actually exceeded the exportation. Exports usually amount to about 2 per cent of the production, but in recent years have been about 1½ per cent. In 1914 the exports were but 9,381,000 bushels and the imports, chiefly from Argentina, about 12,000,000 bushels. Prior to 1900 the exports ranged from 100,000,000 to 200,000,000 bushels per annum, but have steadily declined, owing to the fact that the corn can be more profitably utilized in the production of meats for exportation or domestic consumption. Argentina, which now ranks next to the United States among the world's corn producers, exports more than half of her product, climatic conditions requiring little grain for use in feeding the cattle and sheep, the chief factors in her live-stock industry. Argentina's production, however, is but about one-tenth that of the United States, her largest crop, that of 1912, having been but 296,000,000 bushels against 3,124,746,000 in the United States in that year. Mexico ranked third in 1912, with 190,000,000 bushels, and Hungary fourth, with 177,000,000 bushels.

Corn is utilized in the preparation of more than 100 different articles. Its chief value is as food for man and domestic animals. (See below.) The husks are used in making mattresses, especially in the corn-growing regions. The outer portion of the stalk is used in paper manufacture, and the pith is employed in making pyroxylin varnishes, guncotton, and other high explosives. Owing to its great resilience, porosity, and absorptive power, the pith has also been used in the construction of war vessels, compressed blocks of it being packed behind the outer armor plate to absorb the water and close the aperture in case the plate is pierced by a projectile. The cobs are often ground up for feed, but they are generally used for fuel and are also employed to a considerable extent in the manufacture of tobacco pipes. The principal and most common product of the grain is the flour, or corn meal, which is either white or yellow, according to the variety of corn from which it is made. Nearly all the starch and large quantities of glucose, whisky, and alcohol manufactured in the United States are made from corn. In connection with the manufacture of these various substances a number of by-products are obtained which are generally used for feeding purposes. (See GLUTEN MEAL AND GLUTEN FEED.) Maize or corn oil is obtained from the germ which is extracted from the kernel in the manufacture of starch, glucose (q.v.), and some kinds of meal. The oil expressed from the germ is a light, clear, amber-colored fluid, which may be used for culinary, mechanical, and lighting purposes. It is used to some extent in the manufacture of soap and for making a substitute for rubber.

Sweet Corn or **Sugar Corn** (*Zea saccharata*), generally considered a garden vegetable, is extensively grown in home gardens and for marketing and canning. As a vegetable, it is used while the kernels are plump and well filled out, but still containing milky juice. The ripened kernels have a wrinkled appearance. Sweet corn is adapted to any soil suitable for field corn, though more attention is given to manuring. A warm, rich, sandy loam is considered most desirable. On the northern limits of the corn belt sweet corn is grown as a field crop because of its rapid growing and early maturing habits. Some of the smaller and earlier sorts develop in 70 days; the later varieties require 90 to 100 days. According to the census, the amount grown for canning purposes in 1909 produced 7,451,265 cases, each containing two dozen two-pound cans. Corn for canning is grown mostly in Illinois, Maine, Iowa, New York, Ohio, and Maryland.

Popcorn (*Zea everta*) is characterized by small ears, seldom exceeding 6 inches in length and 1½ inches in diameter, small kernels, and an excessive portion of hard, flinty endosperm in the seed. This latter is supposed to give the property of popping, which is the complete turning inside out of the kernel on the application of heat, by the explosive expansion of steam formed (under pressure, owing to the hard wall of the kernel) from the minute quantities of water in the cells of the interior portion of the grain. Through popping the kernels become very much enlarged, so that a pint of kernels before popping makes six to eight quarts after popping. The popped kernels are pure white and are eaten out of hand, usually salted and often with the addition of a little melted butter, or mixed with sirup and pressed into balls or cakes to be eaten like confectionery. Popcorn requires about the same soil and treatment as field corn.

Feeding Value of Maize. Corn is of the greatest importance and is extensively used in the feeding of farm animals because of the variety and cheapness of feeding stuffs which it furnishes. The uncured plant in different stages of maturity is used as forage; corn shives (i.e., the stalks from which the pith has been removed) have recently been used to some extent; the ripened grain, whole or ground, is fed to all classes of farm animals, often on the cob and often ground with the cob as corn and cob meal; various by-products from the manufacture of starch, glucose, corn breakfast foods, etc., are also largely employed. As a food for man, corn is used cracked or crushed as hominy, and finely ground, both bolted and unbolted, as meal. From white corn, flour is made by grinding the grain after the removal of the germ and some of the outer envelope.

AVERAGE COMPOSITION OF A NUMBER OF CORN PRODUCTS

	Water	Protein	Fat	Nitrogen-free extract	Crude fibre	Ash
	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent
Corn fodder (green)	79.3	1.8	0.5	12.2	5.0	1.2
Corn fodder (cured)	42.2	4.5	1.6	34.7	14.3	2.7

* Dried artificially. † Trace.

The composition of these materials and some others mentioned later is shown in the table above.

Like all green crops, corn fodder has a high water content. It owes its nutritive value principally to the carbohydrates which it contains. It is also useful as a feeding stuff because it is succulent, gives necessary bulk to a ration, and is relished by animals. Dried corn fodder and stover are similar in composition to hay and are very valuable feeding stuffs, but unless cut fine or shredded and otherwise properly handled, a considerable portion may be wasted when fed. It often lacks flavor, and since it is chiefly a carbohydrate food, a one-sided ration, it should be fed with material rich in protein (i.e., concentrated feeds). Its palatability may be increased by moistening with water and sprinkling with bran and steaming. The best results are said to be obtained when only about one-third of the coarse fodder consists of stover. According to reports of the United States Department of Agriculture, the corn stover crop of the United States in 1904 was nearly 92,000,000 tons, much larger than the hay crop.

Corn silage, which resembles the green crop in composition, is wholesome and is relished by farm animals. The grain is especially rich in carbohydrates, principally starch, but contains considerable protein and some fat. Contrary to popular opinion, there is no marked difference in the composition and feeding value of white and yellow corn, or dent and flint corn. Individual specimens of either sort vary more widely than do the averages for the different groups. Corn is used in rations for maintenance, for the production of milk, for fattening, and for feeding draft animals. It is a universal feed for pigs in the United States, a bushel being considered sufficient, when fed alone, to produce on an average 11 pounds of pork. It is also widely used in fattening steers, beef cattle, and poultry, and is very satisfactory for the grain portion of a ration for horses, cows, and sheep. The commercial by-products like gluten meal are rich in protein and are valuable feeding stuffs. Corncobs possess considerable nutritive value, and when ground with the kernel the resulting meal is highly valued. Corn products compare favorably as regards digestibility with other similar feeding stuffs. The coefficients of digestibility of a number of them are on page 701.

Value of Maize as Food for Man. Corn ranks high in comparison with other cereal grains as a food for man. Large quantities are eaten in the United States, in southern and eastern Europe, and in the Orient, but it is little known in northern Europe. Corn meal, made into corn bread, mush, and many other foods, is wholesome and nutritious. It cannot be leavened with yeast like wheat flour in bread making, as the corn does not possess gluten, and the proteids of the maize kernel have other properties than those which characterize gluten. Large quantities of corn are consumed in the form of hominy and other breakfast foods. So far as experiments show, corn is well assimilated by man and, judged by composition, digestibility, palatability, and wholesomeness, is worthy of the high opinion in which it is held.

Green sweet corn, either fresh, canned, evaporated, or dried, commonly eaten as a vegetable in the United States, resembles other succulent vegetables in composition, being rich in carbohydrates. Popcorn, also widely used, closely resembles other varieties in composition, but after popping differs in composition from the raw chiefly in having a low water content. Cornstarch and corn oil, manufactured products, are used in cookery, the former extensively.

AVERAGE COEFFICIENTS OF DIGESTIBILITY OF A NUMBER OF CORN PRODUCTS

	Dry matter	Protein	Fat	Nitrogen-free extract	Crude fibre	Ash
	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent

A disease (*pellagra*) has been attributed to the use of corn, which investigation seems to show is due to molding or spoiling of the grain. This has not been proved, and other theories are also held.

Bibliography. MAIZE BEER. See BEER; CHICA.

MAIZE OIL, or CORN OIL. See MAIZE.

MAIZEROY, mȧ′z′-rwä′, RENÉ, BARON (1856–). A French romancer who wrote under the nom de plume Maizeroy, the name of a branch of his family, though his own was Toussaint. He was born at Metz, was educated at the college of St. Clément, the Toulouse Lyceum, and the St. Cyr military school, whence he entered an infantry regiment as sublieutenant in 1877, resigning three years later to take up literature as a profession. He began with military subjects: *Souvenirs d'un Saint-Cyrien* (1880); *Le capitaine Bric-à-Brac* (1880); *Au régiment* (1885); *Amours de garnison* (1886); *La vie de soldat* (1887); *Souvenirs d'un officier* (1888); *Billets de logement* (1888). After a course of journalistic writing for the *Gaulois, Figaro, Gil Blas, La Vie Moderne*, and *Clairon*, he wrote many romances, such as the series entitled *Les amours défendues* (1884), another called *Les Parisiennes* (1883–90), and a third, *La grande bleue* (1888), which contains sea studies. His sketches of Parisian life include: *Les malchanceux* (1880); *Le mal d'aimer* (1882); *Celles qui osent!* (1883); *Petites femmes* (1885); *La fin de Paris* (1886); *Lalie Spring* (1887); *Des baisers du sang* (1898); and he also wrote plays such as *Le miroir* (1892) and *Papa la Vertu* (1899). Among his later novels are: *Le marchand de déesses* (1905); *La remplaçante* (1906); *Education amoureuse* (1908); *Mademoiselle* (1911); *L'Amour en danger* (1912).

MAJANO, BENEDETTO DA. See BENEDETTO DA MAJANO.

MAJANO, GIULIANO DA. See GIULIANO DA MAJANO.

MAJ′ENDIE, SIR VIVIAN DERING (1836–98). A British artillery officer and authority on explosives. He was born at Pipe Grange and was commissioned in the Royal Artillery in 1854, seeing active service in the Crimean War and winning the medal with clasps and the Turkish medal. He achieved further distinction in the Indian Mutiny and retired as colonel in 1882. In 1880 he was created Companion of the Bath and in 1895 Knight Commander. His service also included 10 years at Woolwich Arsenal, and in 1871 he was attached to the Home Office as Inspector of Gunpowder Works under the Gunpowder and Nitroglycerin acts. Largely instrumental in drafting the British Explosives Act of 1875, he was, on its being made law, appointed Chief Inspector of Explosives and held this office until his death. His bureau was charged with the supervision and regulation of the manufacture, storage, transportation, and importation of explosives in Great Britain, the object being so to safeguard the industry and its products as to reduce to a minimum the casualties attending it. The 22 annual and 50 special reports bearing Majendie's name have served as models to the officials of other countries in which such organizations have since been created.

MAJ′ESTY. See TITLES OF HONOR.

MAJLÁTH, moi′lät, JÁNOS. See MAILÁTH, JÁNOS.

MAJOLICA, or **MAIOLICA,** mȧ-jŏl′ĭ-kȧ *or* mȧ-yŏl′ĭ-kȧ (It., variant of *Maiorca*, Sp. *Mallorca*, Majorca). The name was at first applied to Hispano-Moorish lustred faïence brought into Italy from western Spain via Minorca, then to faïence made in Italy chiefly during the fifteenth and sixteenth centuries. The clay vessel was first fired, then coated with an opaque tin enamel, upon which the decoration was painted, and again fired. The lustre was a final coating of alkaline glaze to protect the design and increase the brilliancy of color. A native mediæval ware, covered with a simple slip, and with Gothic decorative motifs, had been manufactured in various parts of Italy during the thirteenth and fourteenth centuries. The Hispano-Moresque influence is first and chiefly apparent in the potteries of Florence of the early fifteenth century. The factory at Cafaggiolo, near Florence, which was active from the later fourteenth century for two centuries, produced a ware remarkable for deep blue and strong yellow glazes. During the later fifteenth and throughout the sixteenth century Faenza was the most productive and one of the most important centres. Its ware is especially known for its deep blue background; its most famous factory was the Casa Pirota. Deruta (near Perugia) produced a ware famous for its lustres; Urbino was known by its arabesque and grotesque decorations and figure compositions; while Gubbio was the great centre for lustres, not only for its own ware, but for those of all other potteries. The forms of the vessels are often refined, as in the jars painted with the names of medicaments and intended for the dispensary of the great monastery or of the ducal palace; as well as in certain vases and platters of more purely decorative character. The greater number of pieces are plates and dishes, often deep, and many of these have peculiar forms, as when a deep, almost hemispherical bowl is surrounded by a broad, flat marli, the whole upper side being painted in one design. The forms, however, are not more graceful nor do they involve more elaboration of design than in other far inferior wares; the painting, on the other hand, is altogether unique in the history of decorative art. In this way, while the forms were kept simple and on the whole severe, the painting grew more and more splendid in pigments and also nobler in composition, both in line and in color.

The decorations are of many types; thus, in one large round dish the whole surface will be covered minutely with arabesques and grotesques, derived, together with the animal and human forms mingled with them, from ancient Roman examples, and akin to those used by the painters of the school of Raphael in Rome. Another dish of about the same size may have but a single portrait head, perhaps of a lady, filling the whole disk, the colors being those of nature as nearly as obtainable, and a scroll with some laudatory or amatory motto forming a part of the background, between the convolutions of which a grave neutral color is worked in. Other similar plates or dishes have biblical or historical scenes treated freely and with reference in many cases to important mural paintings of the time. Again, others have the human figure nude, or nearly nude, studied from drawings or prints by artists of the same epoch, notably certain engravings of Marcantonio Raimondi, after designs by Raphael.

The introduction, about 1520, of lustre colors in imitation of the Hispano-Moresque wares added greatly to the brilliancy of the effect. The greatest master in such lustre painting was Giorgio Andreoli (q.v.), who possessed the secret of the ruby lustre, which died with him. His work is generally identified with the manufacture at Gubbio. The first half of the sixteenth century saw the highest development of the potter's skill, after which the art declined.

These splendid wares have been copied in modern times, especially in Italy, and with some success; but they have always obtained very high prices. Fine ancient pieces bring from $1000 to $10,000 for a single piece, the rate being governed mainly by the complex character of the design and the brilliancy of color. Rich collections of Italian majolica ware are to be found in the museums of Italy, particularly at Florence and in the provincial towns, and in the museums of London, Paris, Germany, and Austria. The finest in America, and indeed in the world, is that of J. Pierpont Morgan, now on loan in the Metropolitan Museum, New York.

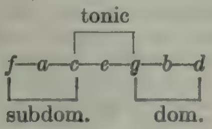
The term "majolica" is used by modern manufacturers for glazed hard pottery intended for use in decorative architecture, for garden seats and outdoor work generally. This ware is not often of much artistic merit. The forms are inferior and the colors are limited to those which will bear the greatest heat of the furnace, and which are therefore very resistant to external influences. In fact, for this purpose stoneware with glazes especially prepared for it is found to be a better material. See STONEWARE.

Very beautiful single examples are given in chromolithography in Labarte, *Histoire des arts industriels* (2d ed., Paris, 1872–75), and in the Spitzer collection, edition in six folio volumes (Paris, 1890–92). See STONEWARE.

MA'JOR (Lat., greater), or MAJOR TERM. A name applied to the predicate of the conclusion of a syllogism (q.v.); it also occurs in one of the premises, which for this reason is called the major premise.

MAJOR (Lat. *major*, greater). The rank next above a captain and below a lieutenant colonel. In the United States the command appropriate to the grade is: infantry, a battalion; cavalry, a squadron; artillery, a battalion. See FIELD OFFICER; RANK AND COMMAND.

MAJOR. A term in music applied to intervals and modes. 1. All intervals which are not perfect are distinguished as major or minor. The former contains always one semistep more than the latter: c—e (5 semisteps) is a *major* third, c—e♭ (4 semisteps) a *minor* third. 2. The major mode is the one which is founded upon the major scale. This scale contains the major third and two semisteps between the 3 and 4 and 7 and 8. Thus: c, d, e, f, g, a, b, c. Modern music conceives a mode as a system of three fundamental chords which contain all the tones properly belonging to the scale of that mode. These chords are the tonic, dominant, and subdominant. In the major mode all these chords are major, i.e., they have the major third. The major scale, as represented by its fundamental chords, presents itself then in this form:



See MINOR.

MAJOR, CHARLES ("EDWIN CASKODEN") (1856–1913). An American lawyer and popular novelist, born at Indianapolis, Ind. He was educated in the common schools of Shelbyville and Indianapolis, studied law and practiced it at Shelbyville, his home. He first became known by his extraordinary popular success *When Knighthood was in Flower* (1898), which was followed by *The Bears of Blue River* (1901); *Dorothy Vernon of Haddon Hall* (1902); *Yolanda, Maid of Burgundy* (1905); *Uncle Tom Andy Bill* (1908); *A Gentle Knight of Old Brandenburg* (1909); *The Little King* (1910); *Touchstone of Fortune* (1912).

MAJOR, mà′yôr, GEORG (1502–74). A Lutheran theologian. He was born at Nuremberg and studied theology at Wittenberg under Luther and Melanchthon; was rector at Magdeburg and Eisleben; professor of theology and court preacher at Wittenberg in 1536; represented the Protestants in colloquy at Ratisbon in 1546. When the Schmalkald War broke out he left Wittenberg and was appointed superintendent and court preacher at Merseburg (1547), but at the close of the war he returned to Wittenberg. In 1551 he actively supported the doctrine of the Leipzig Interim, that good works are necessary to salvation, in opposition to the strict Lutherans, who denied that proposition. Amsdorf assailed him, declaring that good works are or may be detrimental to salvation. In consequence of the controversy Major removed to Wittenberg, and he died there, Nov. 28, 1574. Towards the close of his life he became involved in the Crypto-Calvinistic controversy. (See CRYPTO-CALVINISTS.) A portion of his works, comprising homilies and commentaries on the Gospels and Pauline Epistles, was published in 1569.

MAJOR, or **MAIR,** mâr, JOHN (1469–1550). A Scottish historian and scholar. He was born at Gleghornie, East Lothian; studied at Cambridge and Paris, and spent his life teaching alternately at Paris and in Scotland, mostly at Glasgow and St. Andrews universities, and preparing books for the press. He was a teacher of both John Knox and George Buchanan, but had no sympathy with the Reformation, though he desired ecclesiastical reform. He published many books, all in Latin, upon varied subjects, and is best known to-day by his *History of Greater Britain, both England and Scotland* (1521), which was the first attempt to write Scottish history in a critical spirit. Consult the translation prepared by Constable for the Scottish History Society (Edinburgh, 1892), which contains a life and bibliography.

MAJOR, RICHARD HENRY (1818–91). An English geographer, born in London. In 1844 he was appointed assistant in charge of the maps and charts of the British Museum, and in 1867 he became keeper of the maps and plans. From 1849 to 1858 he was honorary secretary of the Hakluyt Society, for which he edited, with translation, *Select Letters of Christopher Columbus* (1847, 1878), *Early Voyages to Australia* (1859), and several other valuable works. He was also honored by the vice presidency of the Royal Geographical Society. For his *Life of Prince Henry of Portugal* (1868), the *Bibliography of the First Letter of Columbus* (1872), and other publications on the early Portuguese and Italian discoveries, he was decorated by the rulers of Portugal, Brazil, and Italy. He died at Kensington, June 25, 1891.

MAJORANO, mä′yô-rä′nô, GAETANO. See CAFFARELLI.

MAJOR′CA (Sp. **MALLORCA,** mà-lyôr′kà). The largest of the Balearic Islands (q.v.). It lies 105 miles east-southeast of the mouth of the Ebro, the nearest point of the Spanish coast, and in the middle of the Balearic group, with Minorca on the northeast and the Pityusæ on the southwest (Map: Spain, G 3). Area, 1352 square miles. The coasts are nearly all rocky, rising on the northwestern side into steep, rough, and arid mountains, reaching a height of 4768 feet in Mount Torella. The south coast is lower and indented with bays, that of Palma affording a good harbor. The whole southern half of the island is finely diversified with hills and plains, which are fertile. There are extensive vineyards. The climate is healthful. The inhabitants, who resemble the Catalans in their appearance and manners, are hospitable and industrious, and mostly engaged in agricultural pursuits. The chief products of the island are marble, slate, plaster, the common cereals, oranges, silk, lemons, oil, wine of excellent quality, olives, and aromatic herbs. Pop., 1900, 248,194; 1910, 264,231. The capital is Palma (q.v.), situated on the south coast and connected by a railway with La Puebla and Manacor in the interior.

MA′JOR DO′MUS, or MAYOR OF THE PALACE. Originally the title of a royal steward under the Merovingian line of Frankish kings. His proper function was to be the overseer of all the royal estates; he was also at the head of the royal household, and consequently had authority over all who served in the palace. Soon the mayors came to preside over the royal courts of justice and to lead the army. There was a mayor for each of the Merovingian kingdoms of Austrasia, Neustria, and Burgundy. From 643 to 656 Grimoald was mayor of Austrasia, and on the death of the King tried to have his own son crowned King. He was put to death and Ebroin, mayor of Neustria, became powerful and tried to be the real ruler in all three kingdoms. He was assassinated. In 687 Pepin of Heristhal, who was mayor of Austrasia, after the battle of Testry, became ruler of Neustria also. Pepin was the founder of the Carolingian dynasty. (See CAROLINGIANS.) Both he and his son Charles Martel, who died in 741, were kings in everything but name. The latter's son, Pepin the Short, with the approval of the Pope, became King in name as well as in fact in 751. Consult Brunner, *Deutsche Rechtsgeschichte*, vol. i (Leipzig, 1906), and *Cambridge Medieval History*, vol. ii (New York, 1913).

MAJOR GENERAL. The highest grade in the United States army, the rank next above that of brigadier general. The command appropriate to his grade is a division or, in time of peace, a territorial department. In war he would command a division or a field army composed of two or more divisions, since the grade of lieutenant general (q.v.), formerly the highest, no longer exists in the United States army. See Rank and Command.

MAJOR′ITY (ML. *majoritas*, from Lat. *major*, greater). The period when the legal disabilities and the peculiar advantages and privileges incident to the status of infancy come to an end. A person upon attaining his majority has a last opportunity to disaffirm and avoid legal transactions to which he was a party during the period of his minority and which were voidable because of his disability. Certain privileges of citizenship usually commence at this time. As to the time when a person attains his majority and the privileges which it brings with it, see Age; as to the disabilities and privileges of minority, see Infant.

MAJOR PROPHETS. A name used of the prophets Isaiah, Jeremiah, Ezekiel, and Daniel and of the books of the Old Testament written by them, from the length of their writings. See Minor Prophets.

MAJU′BA HILL. A height of the Drakensberg, about 7000 feet above sea level and 2000 feet above the surrounding land, the northwest point of Natal, South Africa, a few miles northwest of Newcastle, overlooking Laing's Nek, an important pass in the Drakensberg, now followed by the Durban to Johannesburg railroad. It was the scene of the British defeat by the Transvaal Boers on Feb. 27, 1881. The British were surprised, and in the fight that ensued 92 British soldiers, including the commander, Gen. Sir G. P. Colley, were killed and about 150 wounded and taken prisoners. The loss of the Boers in killed and wounded was about 130.

MAKAROV, må-kä′rŏf, Stephen Ossipovitch (1848–1904). A Russian naval officer and scientist, born at Kiev. He entered the navy at 16, commanded an auxiliary cruiser in the Russo-Turkish War of 1877–78, and torpedoed several Turkish vessels. He also, as a naval volunteer, took part in the Turkestan campaign of 1881. Subsequently he carried on important hydrographic studies—in 1881–82 in the Black Sea and Mediterranean, in 1886–89 in the northern Pacific, and in 1894–96 both in the Mediterranean and Far Eastern waters. In 1898 he designed the ice-breaking steamer *Yermak*, in which he made a voyage to Franz Josef Land in 1901. In 1897 he became vice admiral and received command of the Baltic fleet, and from 1899 to 1904 was Governor of Kronstadt. Upon the outbreak of the Russo-Japanese War in February, 1904, he was appointed to the chief command of the Russian naval forces in the Far East, but was drowned on April 13 when his flagship, the *Petropavlovsk*, was blown up and sunk by a mine when coming out of Port Arthur. He wrote *Le vitiaz et l'océan pacifique* (1894), a work on naval tactics, and numerous papers on scientific and naval subjects. See Russo-Japanese War.

MAKART, mä′kärt, Hans (1840–84). An Austrian painter. He was born at Salzburg, May 28, 1840, and went to Vienna in 1858 to study at the Academy, but, dissatisfied with the prevailing methods, he returned after a few months to his native city. Through the munificence of the Prince-Archbishop von Tarnoczy he was enabled to study at Munich, chiefly under Piloty. He visited London and Paris in 1863 and soon after went to Rome with a stipend from the Austrian government. His first work to attract wide attention was the "Plague in Florence," a scene of voluptuous horror, which raised a storm of applause and intense adverse criticism. His "Abundantia" pictures (1870, New Pinakothek, Munich), representing the "Fruits of the Earth" and the "Fruits of the Sea," displayed even greater wealth of color than his former pictures. In 1869, after a prolonged stay in Italy, he settled in Vienna, where the Austrian state erected him a large atelier. In 1873 he completed "Venice Doing Homage to Caterina Cornaro," a colossal painting showing the influence of Tintoretto and Veronese, exhibited in Philadelphia in 1876, and now in the National Gallery, Berlin. The winter of 1875–76, which he spent in Egypt, suggested his "Cleopatra" (1875, Stuttgart Museum), "Antique Hunt on the Nile," and other Egyptian subjects. His most ambitious historical painting, "Entry of Charles V into Antwerp" (1875–78, Hamburg Gallery), for which he made special studies on a trip to Antwerp and Spain in 1877, was awarded a medal of honor at the Paris Exposition of 1878. The last of his larger compositions, "Diana's Hunting Party" (1880, Metropolitan Museum, New York), is one of his best works and is remarkable for its landscape surroundings. His remaining paintings include: "The Five Senses" (1879) and "Triumph of Ariadne" (Vienna Museum); "Summer" (1881, Dresden Gallery); "Spring" (1884), his last creation. Makart was appointed professor at the Academy of Vienna in 1879. He was preeminently a decorative genius, a brilliant improviser rather than a well-trained painter, a gorgeous colorist, but often weak in draftsmanship. His aim was the cult of sensuous beauty, but his riotous fancy lacked the sustaining power of an intellectual basis; all simplicity and repose are lost in his striving after effectiveness. Yet with all his shortcomings he was one of the most imaginative artists of modern times. He was the first to bring back the German school to the study and practice of color.

Consult: F. G. Dumas, in *Illustrated Biographies of Modern Artists* (Paris, 1882–88); Lützow, *Hans Makart* (Leipzig, 1886); Stiassny, *Hans Makart und seine bleibende Bedeutung* (ib., 1886).

MAKAW′. A small tribe of expert and daring fishers living about Cape Flattery, at the ocean entrance of Puget Sound, northwestern Washington. They are of Wakashan stock (q.v.), having apparently crossed over from Vancouver Island and conquered a territory for themselves on the southern mainland. In former times they were noted for their fierce and warlike character and still keep up their reputation as being among the most daring boatmen along the coast. The women are skillful basket makers. Many of the men have beards, which are said to be due to an admixture of white blood from the crew of a Russian vessel wrecked upon the coast about a century ago. They now number 360, are gathered upon a small reservation, and are fairly civilized.

MAKDALA. See Magdala.

MAK′EMIE, Francis (?–1708). The father of American Presbyterianism. He was born near Rathmelton, County Donegal, Ireland; studied at Glasgow; was licensed by the Presbytery of Laggan in 1681; and went the next year as missionary to Barbados. In 1683 he went to

Maryland and for several years combined commercial traveling with gospel preaching. In 1690 he was on the eastern shore of Virginia. From 1693 to 1698 he was in Barbados. In 1699 he organized the Presbyterian church of Snow Hill, Maryland, and other churches, and served as their pastor. In 1704 he went to London to appeal to the Presbyterians there for money and men. In this he was successful, and in 1706 the first "presbytery" met in Philadelphia. It was not a presbytery in the ordinary sense, however; rather "a meeting of ministers for ministerial exercises," and not subordinate to synod or assembly. On Jan. 19, 1707, he preached in a private house in New York City, Governor Cornbury having refused him permission to preach in the Dutch church. On January 21 he was arrested at Newtown, L. I., for preaching without the Governor's permission and imprisoned in New York till March 1, and then only released on bail. On June 3 he was tried in New York City and acquitted, because he produced his license to preach, received in Barbados, under the terms of the Toleration Act of William and Mary (1689), which was valid in all parts of the realm. Though acquitted he was condemned to pay costs of both defense and prosecution. He died in 1708 in Accomac Co., Va. Consult W. B. Sprague, *Annals of the American Pulpit*, vol. iii (New York, 1858), and C. A. Briggs, *American Presbyterianism* (ib., 1885).

MAKKARI, mäk′kȧ-rē, Ahmed el (c.1585–1631). A Moorish historian, born in Algeria. He was an active religionist and made two pilgrimages to Jerusalem, six to Mecca, and seven to Medina. Yet he found opportunity for the preparation of several works, of which the most important is the *History of the Mohammedan Dynasties of Spain* (in a partial English translation by Gayangos, 2 vols., 1840–43; edited as *Analects sur l'histoire et la littérature des Arabes d'Espagne*, Leyden, 1855–61).

MAKÓ, mŏ′kō. A town in Hungary, capital of the County of Csanád, situated on the right bank of the Maros, 19 miles by rail east of Szegedin (Map: Hungary, G 3). Its most prominent building is the palace of the Bishop of Csanád. The inhabitants are engaged chiefly in agriculture and stock raising. It manufactures bricks and agricultural machinery. There are also a number of oil presses in the town. Pop., 1900, 33,722; 1910, 34,918, largely Protestant Magyars.

MAKOLOLO, mä′kȯ-lō′lȯ. A branch of the Basutos or eastern Bechuanas of Bantu stock, who migrated northward about the year 1835 and subjugated their kinsmen, the Barotse, on the middle course of the Zambezi River in British South Central Africa. Livingstone was the first explorer to penetrate their country. Subsequently the Barotse overthrew their conquerors, massacred the men, and distributed the women and children among the tribes. The Makololo speech, however, was forced largely upon the Barotse by this very circumstance. The only political fragment of the once-powerful Makololo owes its preservation to the sending out of an embassy with Livingstone to the east coast to seek a cure for the King's leprosy, previous to the Barotse uprising. This party settled on the Shire River, below the falls, and has grown to be of some importance.

MAKREM′BOLI′TES. See Eustathius.

MAKRIZI, mȧ-krē′zē̇ (Ar. Aḥmad ibn ‘Alī Taḳī al Dīn al Maḳrizī). A Mohammedan historian (c.1364–1442). His surname, Makrizi, was taken from Makriz, a suburb of Baalbek, where his grandfather had originally lived. Makrizi spent the greater part of his life in Cairo, where he was born. He was taught in Hanafite schools, but joined the Shafiites in 1384. He journeyed to Mecca in 1385, and upon his return was appointed vice cadi and secretary. He then became successively prefect of police, preacher and teacher at various mosques. In 1408 he was sent to Damascus as curator of a hospital and professor at two different schools. He soon, however, retired to private life, giving himself up entirely to literary pursuits. The years 1430–35 he spent with his family in Mecca. Makrizi is our chief authority for the history and topography of Mohammedan Egypt, though he was not overscrupulous and quietly appropriated the works of other scholars. The most important of his works are: (1) *Al Mawâçiz wal-i‘tibār fi dhikr al-Khiṭaṭ wal-Athār*, a topographical history of Egypt, especially of Fostat and Cairo (ed. Bulak, 1854; French trans. by Bouriant, in the *Mémoires de la mission archéologique française du Caire*, 1895 et seq.); (2) *Al-Sulūk lima‘rifat duwal al-Mulūk*, a history of Egypt from 1181 to 1440 (*Histoire des sultans Mamelouks*, trans. by Quatremère, Paris, 1834–44); (3) *Al-Ilmān*, a history of Mohammedan rule in Abyssinia (ed. Rink, Leyden, 1790, and Cairo, 1895); (4) a treatise on Arabic weights and measures (ed. Tychsen, Rostock, 1800); (5) a treatise on Arabic numismatics (ed. Tychsen, Rostock, 1797, and Cairo, 1880; trans. by De Sacy, Paris, 1797). Consult Brockelmann, *Geschichte der arabischen Literatur*, vol. ii (Berlin, 1902).

MALABAR, măl′ȧ-bär. A district of the Madras Presidency, British India (Map: India, B., C 7). It borders the Arabian Sea for 150 miles, extending from lat. 10° 15′ N. to 12° 18′ N.; it is bounded by the native state of Mysore on the northeast and the native state of Cochin on the south. Anciently, under the name Kerala, it included also the district of South Kanara and the native states of Cochin and Travancore. The district of Malabar, 'the land of hills,' is one of the most beautiful and fertile districts of Madras. It has an area of 5795 square miles, exclusive of the few square miles of the politically attached Laccadive Islands. On the east are the Western Ghats, from 3000 to 8000 feet high, interrupted only by the Palghat Gap, 16 miles wide. The climate is fairly healthful, though very damp. In the low country the temperature seldom rises above 90° F. or falls below 70° F.; the mean annual temperature at Calicut is 81° F. The average annual rainfall is 116 inches. About 38 per cent of the total area is under cultivation, and of this about 60 per cent is planted to rice. Next to rice the most important crop is coconuts; other crops are areca nuts, plantains, pepper, cinnamon, ginger, tea, and various vegetables and pulses. In the strict sense famine is unknown, as the southwest monsoon never fails. The population is less agricultural than in other Madras districts, as many are engaged in fishing, fish curing, oil pressing, rice pounding, woodcutting, and the manufacture of palm-leaf hats and umbrellas. About one-third of the area is under forest. Mining at present is unimportant. The population (including that of the attached Laccadives) in 1871 was 2,261,250; in

1891, 2,652,565; in 1901, 2,795,738 (the increase in 10 years being 5.6 per cent); in 1911, 3,015,119 (7.8 per cent). In 1901, 68 per cent of the inhabitants were Hindu, 30 per cent Mohammedan, and 2 per cent Christian. More than one-third of the Mohammedans of the Madras Presidency are in the Malabar district. The prevailing language is Malayalam; about 4 per cent of the people speak Tamil. In 1901, 17.4 per cent of the males and 3 per cent of the females could read and write. The seat of administration is Calicut. Besides Calicut, the district has only six towns, Cochin, Cannacore, Palghat, Tellicherry, Ponnani, and Badagara. Malabar was ceded to the British in 1792, except the Wynaad taluk, ceded 1799. Consult: Williams Logan, *Malabar* (2 vols., Madras, 1887); Wigram and Moore, *Malabar Law and Custom* (ib., 1900); *Malabar District Gazetteer* (ib., 1908); Henry Bruce, *Letters from Malabar and on the Way* (New York, 1909). See Nairs.

MALABAR BLACKWOOD. An East Indian tree. See Dalbergia.

MALABAR COAST. A region of south India inhabited by people speaking the Malayalam language. Its northern limit is variously assigned, but it may be said to extend along the Arabian Sea from Cape Comorin to the northern boundary of the Madras Presidency, with the Western Ghats on the east (Map: India, C 7). It is thus included in the British districts of South Kanara and Malabar and the native states of Cochin and Travancore. The sandy coast is intersected by numerous inlets of the sea, some of which extend as lagoons for considerable lengths parallel to the coast, receive the various mountain streams, and communicate with the ocean by narrow shallow openings. Considerable inland navigation is carried on by native craft and light-draft coasting vessels. During the southwest monsoon of the rainy season (June to September), the sea obstructs the outlets of these lagoons and, swollen by the mountain torrents of the Ghats, they form backwaters which overflow the lowlands in all directions. When the waters recede and evaporate during the dry season the lowlands are cultivated and yield rich crops of rice. The mass of the people are of Dravidian stock, with customs, traditions, and castes of their own. (See Malayalim.) The chief seacoast towns include Mangalore, Cannanore, Tellicherry, Mahé (French), Calicut, Cochin, Mattancheri, and Trivandrum (2 miles from the sea).

MALABARI, măl'á-bä'rê, Behramji Maharbanji (or Merwanji) (1853–1912). An Indian social reformer and journalist, born at Baroda. He taught in a Parsi proprietary school; brought out his first volume of poems in 1875; and was proprietor and editor of the *Indian Spectator* from 1880 until 1900, when this publication was merged with the *Voice of India*. In 1901 he became editor of *East and West*. He devoted much of his life to bettering the condition of the women of India by advocating the abolition of child marriage and of enforced widowhood and by urging the passage of the Age of Consent Act of 1891. Gifted as a writer, he published: *The Indian Muse in English Garb* (1877), poems; *Gujarat and the Gujaratis* (1884); *The Indian Eye on English Life* (1893), an account of his visits to England; *The Indian Problem* (1894).

MALABARS. See Malayalim.

MALABÚYOC, mä'lȧ-bōō'yôk. A town of Cebú, Philippines, situated at the mouth of the Malutuoc River, on the Strait of Tañon, on the southwest coast of the island, 60 miles southwest of Cebú. Pop., 1903, 11,781.

MALAC'CA. A British territory on the southwest coast of the Malay Peninsula, forming a part of the Straits Settlements (Map: French Indo-China, D 6). Its area is about 708 square miles and it consists mainly of low, swampy land, rising towards the interior and producing rice, pepper, and sago. There are tin mines in the interior and tin is one of the principal exports. The capital is Malacca. There is cable connection with Singapore and Penang. The climate is 72° F. to 80° F. in shade, but the capital is fairly healthful. The territory has little attraction except for the sportsman and naturalist. Trade is entirely with Singapore and the Malay States. Revenue in 1910 amounted to $1,342,005. Trade in 1912 equaled $22,114,728. Rubber is now an important product and there are 35 companies with $15,000,000 capital. Para rubber, to the value of $10,353,914, was exported in 1912. Malacca is governed by a resident Councilor subordinated to the government at Singapore. Pop., 1891, 92,170; 1901, 95,487; 1911, 124,081.

MALACCA. The capital of the Territory of Malacca in the Straits Settlements, situated on the southwest coast of the Malay Peninsula, 125 miles northwest of Singapore (Map: French Indo-China, D 6). It was formerly an important commercial port, but has declined owing to the competition of Singapore. Pop., 1891, 16,502; 1901, 15,586; 1911, 21,213. The town was first taken by the Portuguese in 1511 and was later occupied by the Dutch. It became a British possession in 1824, in exchange for the British settlements in Sumatra.

MALACCA, Strait of. The body of water which separates the Malay Peninsula on the northeast from the island of Sumatra on the southwest and connects the Bay of Bengal with the South China Sea (Map: Asia, M 8). Its length is 500 miles and its breadth varies from 50 miles at the southeast to 250 miles at the northwest extremity. Its narrow end is filled with a number of large and small islands, on one of which is the British settlement of Singapore.

MALACCA CANE. A species of cane (*Calamus scipionum*), used in the manufacture of walking sticks. It is imported from Sumatra.

MALACCA WEASEL. A civet. See Rasse.

MALACHI, măl'á-kī (Heb., my messenger). Commonly regarded as the name of the author of the last book of the Minor Prophets in the Jewish canon of the Old Testament. The Greek version, however, read "by the hand of his messenger," and the Targum "by the hand of my messenger whose name is called Ezra the scribe." It is probable that Malachi is neither a proper name nor an appellative of the author of the book, but that it was taken by some editor from iii. 1 and made the title of a book that had no author's name prefixed. The prophecy of Malachi is therefore anonymous. The book falls into two divisions: (*a*) a general presentation of the main theme, followed by a rebuke to the priests (i–ii. 9), and (*b*) a rebuke of the people with occasional references again to the sins of the priests (ii. 10–iv. 6). After a brief introduction emphasizing Yahwe's love to Jacob as proved by his hatred of Esau indicated by its lot, the prophet addresses the priests, rebuking them for their heartless, mercenary, and corrupt services and especially for their allowing inferior or unclean offerings to be presented on the altar. He threatens them with judgments if they persist in their sins, and describes the character of a true priest in contrast with their own. The second part consists of a series of oracles addressed to all the people, who are rebuked for their marriages with the Gentiles and their rejection of the lawful wives of their youth, who were left to weep at the altars of Yahwe. It is maintained by some scholars that this rebuke of unlawful marriages is a simile for the disloyalty of the people towards Yahwe, but the interpretation is forced. The prophet continues by the announcement of the sudden coming of Yahwe, whom the people claimed to seek, but who, in an unexpected coming, would sit in judgment against all transgressors, supplying by His own omniscience swift testimony against them. This represents the prophet's answer to those who declared that Yahwe did not concern Himself with the affairs of the individual. He calls the people to repentance, with the promise of abundant blessings to all who obey. To those who already fear Yahwe he gives the assurance that they shall always be precious in His sight, and closes with the renewed announcement of the appointed judgment, before which great and dreadful day Elijah, the prophet, will come calling fathers and children to repentance as the only way of avoiding the hastening doom. He is also the messenger of Yahwe who will come to purge the Levitic priesthood so that they may offer clean and acceptable sacrifices to Yahwe. The Book of Malachi is a production of the Persian period. The Exile lies in the past and is not even referred to. The temple has been rebuilt and the cult is regularly carried on, but a spirit of religious indifference prevails among priests and people. Mixed marriages are still going on, and the priests use their sacred office for personal aggrandizement. The people, too, are not conscientious in paying their tithes (iii. 8–12). We are therefore transported by this book to the first half of the fifth century B.C., when the evils described, which ultimately led to internal conflicts terminating in the division of the people into several parties, were beginning to set in. This date is also indicated by the recent expulsion of the Edomites from their mountain home by the Nabatæans. The diction of the Book of Malachi is more prosaic than the earlier prophetical discourses and has some pecularities that are regarded as marks of a late date. The style is vigorous without approaching in vividness some of its predecessors. The book is referred to no less than four times in the New Testament (Mark i. 2, ix. 11; Luke i. 17; Rom. ix. 13). Consult, besides the general works on the Minor Prophets, especially the commentaries of G. A. Smith, Nowack, Wellhausen, Marti (1904), and Van Hoonacker (1908); Köhler, *Der Prophet Maleachi* (Erlangen, 1865); J. J. S. Perowne, "The Book of Malachi," in the *Cambridge Bible for Schools and Colleges* (Cambridge, 1889); Torrey, in the *Journal of Biblical Literature* (Boston, 1898); S. R. Driver, "Malachi," in the *Century Bible* (London, 1906).

MALACHITE, măl'ȧ-kīt (from Lat. *malache*, Gk. *μαλάχη, mallow;* so called from the color). A basic cupric carbonate that crystallizes in the monoclinic system. It is of a bright-green color and is commonly found massive, though sometimes in botryoidal or stalactitic forms. Malachite occurs with other ores of copper, frequently as a product of their alteration, and is found in the Ural Mountains, in Tirol, at various localities in France, and elsewhere throughout the world. Specimens in fine mass with acicular crystals occur at Bisbee and Morenci, Ariz. It has long been highly prized as a gem and ornamental stone, especially in Russia, where it is used for inlay work, mantels, table tops, and paneling.

MALACHITE GREEN. See COAL-TAR COLORS.

MALACHOWSKI, mä'la-kôf'skė, STANISLAUS HALENCZ, COUNT (1736–1809). A Polish statesman. He was born at Konskie; became president of the royal court of justice and deputy to the Coronation Diet of 1764; and in 1788 was chosen president of the Four Years' Diet. The chief framer of the constitution of 1791, upon its failure the next year he left the country, subsequently settling on his estates in Galicia. He reëntered politics in 1807; and, when the Grand Duchy of Warsaw was created, he became President of the Senate under the new government of the King of Saxony, Frederick Augustus. His death was greatly mourned by the Poles.

MALACHY, măl'ȧ-kī, SAINT (?1094–1148). An Irish prelate and reformer. He was born probably in Armagh, of the noble family of O'Morgair, educated by a hermit named Imhar O'Hagan, and ordained priest in 1119. He made further studies at the famous school of Lismore, but returned to Armagh to throw himself heartily into the movement for the reformation of the Celtic church. He was chosen Bishop of Connor in 1124. When Celsus, Archbishop of Armagh, was dying, he charged his clergy and people not to elect, according to the prevalent custom, a member of his family, but to choose Malachy. The election was disputed by a kinsman of the late prelate, and it was not till five years later, in 1134, that Malachy was able to enter into undisputed possession of his see, which, however, he resigned in 1137 to return to his former diocese, which he divided into Down and Connor, retaining the former. He still retained a great influence over the development of the whole Irish church. He visited Rome during the pontificate of Innocent II, stopping on his way at Clairvaux, where he made the acquaintance of his future biographer, St. Bernard. The Pope invested him with extraordinary powers as legate in Ireland. Leaving home once more in 1148 to visit Pope Eugenius III at Clairvaux, he died in the arms of St. Bernard, was buried at Clairvaux, and was canonized in 1189.

A singular document passes under the name of the *Prophecy of Saint Malachy*, which professes to give a list of 141 appropriate mottoes for all the popes from 1143 to the end of time. St. Bernard, though he ascribes to Malachy the gift of prophecy, mentions nothing like this; and no earlier date for its existence can be authenticated than 1595, in which year it was printed at Venice. As a matter of fact, however, the mottoes for popes later than that date are often singularly appropriate, either to the character, history, or sometimes to the armorial bearings of the various pontiffs. Thus, that of Pius VI was *Peregrinus apostolicus;* Pius VII, *Aquila rapax;* Pius IX, *Crux de cruce*—the cross of Savoy was indeed a heavy cross to him; Leo XIII, *Lumen in cœlo*—the "light in heaven" has been referred both to the general enlightened policy of his reign and to a blazing comet which appears in chief in his family arms; Pius X, *Ignis ardens;* Benedict XV, *Religio populata.* The few remaining mottoes are: *Fides intrepida; Pastor angelicus; Pastor et nauta; Flos florum; De medietate lunæ; De labore solis; Gloria olivæ.* "Then," the prophecy concludes, "a second Peter shall sit upon the seven hills, and Christ shall return to judge the world by fire." For further details, consult: O'Brien, *Historical and Critical Account of the So-Called Prophecy of Saint Malachy* (Dublin, 1880); Lord Bute, "On the Prophecy of Saint Malachy," *Dublin Review* (ib., 1885); his *Life* by O'Hanlon (ib., 1859) and O'Laverty (Belfast, 1899).

MAL'ACOL'OGY (from Gk. *μαλακός, malakos,* soft + *-λογία, -logia,* account, from *λέγειν, legein,* to say). The science or study of mollusks as animals, in distinction from conchology, which considers only, or mainly, their shells. See Mollusca.

MALACOPTERYGII, măl'ȧ-kŏp'tēr-ĭj'ĭ-ī, or **MALACOP'TERI** (Neo-Lat. nom. pl., from Gk. *μαλακός, malakos,* soft + *πτερύγιον, pterygion,* dim. of *πτερόν, pteron,* wing, fin). One of the two primary divisions of osseous fishes in the system of Cuvier, distinguished by soft or spineless fins, the rays of which are jointed. (See Fin.) The cod is an example. The signification has been modified by Müller, Owen, and others, and the term is now little used. Compare Acanthopterygii.

MALACOS'TRACA (Neo-Lat. nom. pl., from Gk. *μαλακός, malakos,* soft + *ὄστρακον, ostrakon,* shell). One of the major divisions of class Crustacea, Phylum Arthropoda, usually accorded the rank of a subclass; lobsters, crabs, and shrimps are familiar examples. The Malacostraca are usually large organisms, distinguished by a definite and constant organization of the body in three parts: head, thorax, and abdomen. The head comprising five segments bears two pairs of antennæ, one pair of mandibles and two pairs of maxillæ, in addition to the eyes which are paired, and are borne on stalks in the higher orders. The thorax is composed of eight segments, bearing appendages for progression, typically forked; from one to five of the anterior pairs are converted into accessory mouth parts (maxillipeds). The abdomen consists of six segments with limbs, and a tailpiece (telson), although in one order (Phyllocarida, example *Nebalia*) a seventh segment devoid of limbs precedes the telson. The eggs are usually heavily laden with yolk; the larva is rarely a free-swimming nauplius as it is in the more primitive Entomostraca (q.v.). See Crustacea.

MALADE IMAGINAIRE, mȧ'lȧd' ē'mȧ'zhē'när' Lε, (the imaginary invalid). A five-act prose comedy by Molière, produced at the Palais Royal in 1673.

MALAGA, *Sp. pron.* mä'lȧ-gȧ (ancient *Malaca*). The capital of the Province of Malaga in the former Kingdom of Granada, Spain. It is situated at the head of a small bay of the Mediterranean Sea, 64 miles northeast of Gibraltar (Map: Spain, C 4). It is picturesquely located on a fertile plain, amid gardens and vineyards, and surrounded on three sides by mountains. The climate is remarkably dry and equable, the place being protected from the north winds by the mountains and enjoying the tempering influence of the sea breezes. It is a straggling, irregularly built town, with narrow, crooked, and unclean streets and has few interesting features. The old portion is built at the foot of the steep hill of Gibralfaro, surmounted by a Moorish castle, which dates from the thirteenth century and is about the only relic of past times still preserved. The newest portions of the town are more attractive. Near the harbor is a handsome, broad promenade, the Alameda, shaded by fine trees and ending at a beautiful fountain. There are several new avenues laid out along the water front, and the residential district of the Caleta is pretty and well kept. The cathedral is a vast structure of a mixed style of architecture, chiefly Gothic, but very imposing, dominating the whole view of the town from the sea. There is a large bull ring. The intellectual life is centred in the lyceum of literature and art, with a good library and picture galleries. The harbor, which was formerly obstructed, has since 1892 been improved, and there is considerable trade in sugar, wine, oil, lemons, and other agricultural products. There are manufactures of soap and chemicals, ropes, leather, and cloth, as well as several large iron foundries, sugar refineries, and distilleries. Pop., 1887, 134,016; 1900, 131,063; 1910, 136,365.

In ancient times Malaga was an important Phœnician, and later a Carthaginian, colony. Under the Romans, and especially under the Moors, it developed into a strong military station. It was captured in 1487 by Ferdinand and Isabella, after an heroic resistance. The French sacked the city in 1810.

MAL'AGAS'Y. See Madagascar.

MALAGASY SUBREGION. In zoögeography, a subdivision of the Paleotropical or Ethiopian Region, embracing Madagascar and the Comoro, Seychelle, Mascarene, and neighboring islands. This insular subregion is so different in its fauna from the African continent, and has so much that is exclusive, that some zoölogists have placed it in the first instead of the second rank of zoögeographical divisions. Haeckel, indeed, regarded it, theoretically, as the relic of a former hypothetical continent, or archipelago, Lemuria (q.v.), which extended eastward into the Malayan islands. Its extent was supposed to be indicated by the present distribution of the lemur family, but more recent knowledge in regard to the past distribution of this family, derived from fossil remains, shows that the hypothesis is untenable. This theory indicates, however, the most prominent characteristic of the fauna of Madagascar, which is that it is the headquarters of the lemur tribe. Nearly all the other lemurs known (except the African galago) are Malayan, and this fact, together with various other coincidences, leads to the conclusion that there was once some intercommunication. The isolation of Madagascar must, however, have occurred very long ago, even as time is reckoned in paleontology, for the differences between it and Africa are almost as great as those between it and the Orient. Very deep water separates it from Africa, and there could have been little if any interchange of terrestrial life since a very remote period. Its mammalian fauna is rich in lemurs and insectivores—all small animals of ancient types. The only ungulate is a peculiar species of river hog, for none of the antelopes and the like of Africa live there. There are very few and small rodents, and none of the great carnivores; the beasts of prey are altogether of the civet family, the largest of which is the ferocious fossa (q.v.), which is about twice the size of a house cat. In every case the species is peculiar to the island, and in most cases the genus also. Birds are extremely numerous, and on the whole are Ethiopian in character; but many genera and species are wholly restricted to this subregion. Here, too, was the home of many recently extinct birds, such as the epiornis, a relic of an ancient Notogæan tribe, the dodo, solitaire, and so on. (See Bird, Fossil; Extinct Animals.) The reptiles present many purely local forms and curious resemblances to the faunæ of other regions. Of the great colubrine family of snakes, none is of the African type, nor is there a viper; on the contrary, several genera are the same as or similar to those of America. The boas, so characteristic of South America, are represented by Malagasy species, and also the tree snakes (Dendrophidæ); while several families mainly Oriental are represented here (e.g., see Langaha). A similar mixture of types may be found among Malagasy lizards and chelonians—the latter including in the Mascarene Islands the once numerous and very ancient giant tortoises. (See Extinct Animals.) No other part of the world seems to have possessed, when first investigated by Europeans, so many senescent species, most of which have succumbed to civilization. The amphibian fauna of Madagascar has only recently been studied and has been found equally remarkable with the rest, so that Gadow makes it one of the four primary subdivisions of the Southern Hemisphere of the Old World (his "Notogæa"; consult *Amphibia and Reptiles*, London, 1901). There is a mixture of African and Indian forms. The island differs from Africa by the absence of Apoda (limbless batrachians), Aglossa (tongueless frogs), and Bufonidæ (toads). It differs from the Oriental Region in similar absences of certain groups, and has several exclusive forms of its own. Fresh-water fishes and the invertebrate life are not well known, but seem to bear out the former deduction that Madagascar has a fauna which has been very long isolated, and was originally derived from sources which contributed to both Oriental and Ethiopian regions. See Distribution of Animals, and the accompanying maps.

MALAGUETTA (mä'lȧ-gĕt'tȧ) **PEPPER.** See Guinea Pepper; Grains of Paradise.

MALAKANI, mä'lȧ-kä'nė. See Molokani.

MALAKASTEUM. See Osteomalacia.

MALAK'KA. See Malacca.

MALAKOFF, Duke of. The title of Aimable Jean Jacques Pelissier (q.v.), Marshal of France.

MAL'ALAS (Lat., from Gk. Ἰωάννης ὁ Μαλέλα, or Μαλάλα (*Iōannēs ho Malela* or *Malala*), John the Orator, from Syr. *malālā*, eloquent, from *malel*, to speak), Johannes (c.491–578). A Byzantine chronicler, of whose life little is known. His fame is due to the fact that he wrote a chronicle in 18 books, not addressed to scholars but intended for the use of the unlearned. It was popular and was frequently copied during the next five centuries. The beginning and end of the work have been lost, but the part which we have begins with mythical times and extends far enough to include some of the events which happened in Malalas' lifetime. Consult, for the various editions and for bibliography, Krumbacher, *Geschichte der byzantinischen Litteratur* (2d ed., Munich, 1897).

MALAMPAYA (mä'läm-pä'yȧ) **BAY,** or Sound. An inlet of the China Sea, on the northwest coast of the island of Palawan, Philippines (Map: Philippine Is., B 5). It is one of the finest natural harbors in the archipelago. Its narrow entrance can be protected from the rocky headlands on either side, and within is a landlocked harbor, 9 miles long by 4 miles wide, with depths ranging from 36 to 54 feet.

MALAN, mȧ'län', César Henri Abraham (1787–1864). A Protestant divine, born in Geneva, Switzerland. He was educated at the academy in Geneva; was ordained to the ministry of the national church in 1810; and became preacher to the cathedral and a regent of the academy. He preached the Socinian views which prevailed in the Swiss church at the time, till, in 1816, under the influence of American and Scottish friends, he accepted the Trinitarian doctrine. The promulgation of his new faith exposed him to the censure of the authorities and he was excluded from the cathedral pulpit in 1818. After preaching in his own house for a time he became pastor of an independent church called La Chapelle du Témoignage, and was for many years a conspicuous figure in the Protestant life of central Europe. In 1828 he was dismissed from the pulpit of the national church, because he persisted in preaching doctrines not generally accepted. He founded a theological school at Geneva and introduced Sunday schools into Switzerland. He visited almost every country in Europe and became famous as an itinerant preacher. He published a book of hymns, *Les chants de Sion* (1826; with original music, 1841); *Les Mômiers, sont-ils invisibles?* (1828); *Le témoignage de Dieu* (1833); *L'Eglise romaine*, which was published in English in New York in 1844; *Les grains de sénevé* (1846). His *Life* was published by his son, Solomon César Malan, in Geneva in 1869 and translated into English in the same year.

MALAN, Solomon César (1812–94). A British Orientalist, born at Geneva, Switzerland. He graduated from Oxford University in 1837, having specialized in the study of Sanskrit, Arabic, Hebrew, and other languages. He then served until 1840 as a lecturer at Bishop's College, Calcutta; while there he gained a knowledge of the Tibetan and Chinese languages. After holding several other charges, he was curate at Broadwindsor, Dorset, from 1845 to 1886. He made many translations from the Armenian, Coptic, and Georgian. The University of Edinburgh gave him the degree of D.D. in 1880.

MALANGA, mȧ-läṉ'gȧ. See Dasheen.

MAL'APROP, Mrs. (Fr. *mal-à-propos*, not to the purpose). A character in Sheridan's play *The Rivals* (1775), who has a ludicrous habit of using wrong words which resemble the right ones more or less; as when she speaks of a person as "a *progeny* of learning," or of "an *allegory* on the banks of the Nile."

MALAP'TERU'RUS (Neo-Lat., for **malacopterurus*, from Gk. *μαλακός*, *malakos*, soft + *πτερόν*, *pteron*, wing, fin + *οὐρά*, *oura*, tail). A genus of African catfish (q.v.), in which in place of a free dorsal fin there is a soft fatty fin near the tail. Two species are known, viz., *Malapterurus electricus* and *Malapterurus beninensis*, both remarkable principally for their electric organs and properties. See Electric Fish.

MÄLAR, mȧ'lär, or **MAELAR.** One of the largest and most beautiful lakes in Sweden, stretching for 70 miles westward from Stockholm, with a breadth of from 2 to 23 miles and an area of about 450 square miles (Map: Sweden, F 7). Its waters are nearly on a level with the Baltic Sea, into which they are discharged by channels running through and around the city of Stockholm. A canal connects it also with Lake Hjelmar. The lake contains over 1200 islands, and the scenery along its shores is much varied with wood, lawn, and cliffs, and adorned with castles, country seats, and villas. The surrounding country is fertile and populous, and upon the shores stand the towns of Enköping, Vesterås, Strengnäs, and a number of villages.

MALA'RIA (from It. *mal' aria*, bad air, from *mala*, fem. sing. of *malo*, from Lat. *malus*, bad, and *aria*, from Lat. *aer*, from Gk. *ἀήρ*, air, from *ἄειν*, *aein*, to blow) and MALARIAL FEVER. This disease was until recent years regarded as a poisonous emanation (whence the name) from the soil of certain localities, but is now definitely known to be one of the specific infectious diseases and to be caused by an animal parasite peculiar to the blood of man and mosquitoes—the *Plasmodium malariæ*. This parasite, discovered in 1880 by Laveran (q.v.), belongs to a class of protozoa called *hemocytozoa* or *hemosporidia*, which attack and develop in the red blood corpuscles of animals, birds, and fish, and of which numerous species are known. In the human blood several varieties of the parasite have been distinguished, each associated with a definite type of fever. These are the parasites of tertian, quartan, and æstivo-autumnal fever, named by Schandinn *Plasmodium vivax*, *Plasmodium malariæ*, and *Plasmodium immaculatum* respectively. The æstivo-autumnal form has two varieties, the quotidian and the tertian. It was first pointed out by Golgi that the tertian and quartan parasites exist in the blood in great groups, all the members of which are at approximately the same stage of development. An entire group, for example, undergoes sporulation within a few hours' time, and this sporulation is always accompanied by the malarial paroxysm. The tertian parasite requires about 48 hours to accomplish its life cycle and produce spores; the quartan about 72 hours; so that in a single infection with one or the other of these parasites we observe the characteristic malarial paroxysm on every third and every fourth day respectively. Double infection, i.e., the introduction of two separate groups of parasites at different times, may occur, however, and produce daily paroxysms or attacks on two successive days, with a day's intermission, etc. The exact duration of the life cycle of the æstivo-autumnal type of parasite is less definitely understood. Sporulation may occur at irregular intervals, or may take place continuously, and the resulting fever is correspondingly irregular and sometimes almost continuous. The plasmodium may be observed in the blood of individuals suffering from an attack of malarial fever, lodged in the red blood corpuscles. It is essentially a parasite living upon and within these cells. It begins its life cycle as a small round or oval hyaline amœboid body. The tertian variety is the largest and is about the size of a red corpuscle ($\frac{1}{3200}$ of an inch in diameter). The æstivo-autumnal variety is less than half that size, the quartan somewhere between the two. The red corpuscles attacked become expanded or shrunken and decolorized, and the pigment collects in clumps of granules. Later on long, active processes called *flagella* develop from the full-grown parasite and move about freely in the blood. These are believed to be the sexual elements.

Of the 50 or more species of mosquitoes belonging to the genus *Anopheles*, the following, according to Craig, have been shown experimentally to transmit the disease: In Africa, the *A. costalis*, *A. paludis*, *A. funestus;* in India, *A. sinensis*, *A. Rossii*, *A. culicifacis*, *A. Theobaldi*, *A. barbirostris;* in Europe, *A. superpictus*, *A. maculipennis*, *A. bifurcatus;* in America, *A. maculipennis*, *A. argyrotarsus*. Walker and Barker, of the Bureau of Science at Manila, announced in 1914 the discovery of a mosquito of a different variety from that usually carrying malaria, which had caused unexplained epidemics in the archipelago. This mosquito they named *Myzomia febrifera*. Bass and Johns in 1912 succeeded in cultivating the plasmodium in human serum and ascitic fluid.

Individuals who have suffered from repeated attacks of malaria, especially if the disease has not been properly treated, fall into a peculiar state called malarial cachexia, the characteristic symptoms of which are a greatly enlarged spleen and more or less severe anæmia. Sufferers from this condition have a peculiar yellowish or grayish color of the skin; there are loss of appetite, diarrhœa, emaciation, and general nervous exhaustion. The condition is especially frequent in children living in the tropics.

That insects might be the means of transmitting malaria was suggested nearly 2000 years ago by Varro and Columella. Nott in 1848 was satisfied with the fact, but King, of Washington, in 1882, was the first to advocate the theory effectively and to marshal the evidence in its favor. Laveran also in 1884 supported his contention, and in 1894 Manson stated his belief that malaria was transmitted only by the mosquito. A year later Ross, of the Indian Army Medical Service, observed the development of the æstivo-autumnal parasite in the body of the mosquito. In 1898 Bignami began inoculation experiments, and finally succeeded in producing an attack of malaria in man by means of infected mosquitoes. Bignami's experiments were with the æstivo-autumnal parasite. Simultaneously Bastianelli, Bignami, and Grassi transmitted a double tertian infection in man through the bite of an infected mosquito. Until the truth of the mosquito theory was established the only protection against malaria was quinine. Now, however, a much more effective defense is possible for those compelled to live in malarious districts. This consists in shielding themselves from the bites of mosquitoes, especially at night, by the use of nets and screens; in waging a constant warfare upon the insects by draining stagnant pools and marshes where they breed; and in destroying their larvæ by the liberal use of petroleum during the malarial season. See INSECTS, PROPAGATION OF DISEASE BY.

Malaria has a wide geographical distribution. No continent is entirely free from it, and certain parts of the tropics are practically uninhabitable by reason of the severe types of fever which prevail. In Africa the west coast is the worst district. In Asia many portions of India, especially along the valleys of the Ganges and Indus rivers, and parts of China and Persia, are malarious. In Europe the disease prevails in Holland, North Germany, the west coast of Italy, and the fen districts of England. In North America it occurs chiefly along the lower Atlantic seacoast and in the Gulf States. The disease is always associated with warm, marshy soils, estuaries, badly drained low-lying districts, and tracts of land rich in vegetation, which offer suitable breeding places for the mosquito.

A typical attack of malaria, or paroxysm, is characterized by three well-defined stages. The *cold* stage is preceded by a headache, yawning, and general malaise; gradually the patient begins to shiver, and in the height of the chill shakes violently. The temperature rises to 102 or even to 105 or 106 degrees. This stage lasts from 10 minutes to an hour, and is followed by the hot stage, during which the coldness of the surface disappears and the skin becomes flushed. In from one-half to three or four hours the *sweating* stage sets in. Beads of perspiration appear on the forehead, and the whole body is bathed in a copious sweat. The fever and headache disappear, and within an hour or two the patient sinks into a sleep and the paroxysm is over.

In the pernicious form of malaria which occurs in the tropics and is always associated with the æstivo-autumnal parasite, the attack is sudden and violent, with intense cerebral disturbance, either delirium or coma. This form is generally fatal. The only remedy which can be relied on in this disease is quinine, which may be regarded as a specific. Large doses have sometimes to be given in the severer types of the affection. For the profound anæmia following long-continued infections, iron and arsenic are given.

Bibliography. Scheube, *Diseases of Warm Countries* (London, 1903), containing a complete list of articles on discoveries in malaria up to that time; R. Ruge, *Introduction to the Study of Malarial Diseases* (New York, 1905); R. W. Boyce, *Mosquito or Man?* (2d ed., ib., 1910); William Osler, *Principles and Practice of Medicine* (ib., 1912); G. E. Henson, *Malaria* (St. Louis, 1913); W. B. Herms, *Malaria, Cause and Control* (New York, 1913); R. H. von Ezdorf, *Malarial Fevers* (Washington, 1913–14), a valuable series of papers dealing with the disease chiefly in the Western and Southern States. See AGUE; HYGIENE, *Military Hygiene;* INTERMITTENT FEVER; MIASMA; MOSQUITO; PANAMA CANAL; REMITTENT FEVER.

MALASPINA, mä′lȧ-spē′nȧ, SABA. An Italian historian, chancellor under Pope John XXI. He was of the same stock as Ricordano Malaspina (c.1200–81), the author of an *Istoria fiorentina;* and wrote *Res Siculæ*, dealing, from the side of the Guelphs, with the period between 1250 and 1276.

MALASPINA GLACIER. One of the largest of the remarkable group of Alaskan glaciers, a great plateau of ice formed by the confluence of several valley glaciers that flow down the slopes of the St. Elias Alps. With its tributaries, which include Seward Glacier on the east, Agassiz in the centre, and Tyndall and Guyot on the west, it covers an area of 1500 square miles and has a front along Yakutat Bay and the Pacific of 70 miles. Its surface is undulating or broken, traversed by streams in summer, and its margins are heavily mantled with morainal material in which nestle many lakes. The marginal moraines are partly forested, although beneath there is 1000 feet or more of solid ice. The ice flows southward and as it meets the sea it breaks off in great masses that float away as bergs, to the danger of navigation.

MALATESTA, mä′lȧ-tĕs′tȧ. The name of an Italian family settled in the Romagna. The principal branch of the family ruled in Rimini, which they entered in 1216; in 1237 Giovanni was elected podestà; in 1247 Malatesta de Verrucchio succeeded him and after various vicissitudes became supreme ruler after 1295. He was an active Guelph partisan, as was his son and successor, Malatestino, who annexed Cesena. One of his brothers, Giovanni, was the husband of Francesca da Rimini, daughter of Guido da Polenta, the pathetic story of whose love for Giovanni's brother, Paolo, is told in Dante's *Inferno.* Malatestino's brother, Pandolfo I, succeeded him and continued the traditional policy of his family in supporting the Pope against the Ghibellines. During the Renaissance the family was among the most powerful in Italy. It was connected by marriage with the houses of Urbino and Montefeltro, and it had possession at one time of Bergamo and Brescia. Perhaps the most celebrated of this family is Sigismondo, who died in 1468. He was a patron of artists and authors, the founder of a library at Rimini, and a skillful general, who fought for himself as well as for Venice, Naples, Siena, Florence, and Aragon. He made war upon the Pope and was excommunicated in 1460. He was a son-in-law of Francesco Sforza. The last Malatesta who was Lord of Rimini was Pandolfo IV, who sold Rimini to the Venetians in 1503. Consult: C. E. Yriarte, *Un condottiere au quinzième siècle* (Paris, 1822); Edward Hutton, *Sigismondo Pandolfo Malatesta, Lord of Rimini: A Study of a Fifteenth Century Italian Despot* (London, 1906).

MALATIA, mä′lȧ-tē′ȧ. The capital of a sanjak and a garrison town in the Vilayet of Mamuret el Aziz, Asiatic Turkey, situated at an altitude of 2900 feet, about 10 miles southwest of the Euphrates and about 90 miles northwest of Diarbekir (Map: Turkey in Asia, D 2). It is a well-built town, with a fine khan and extensive bazars. Fruit culture constitutes the chief industry, and the town is of considerable commercial importance. There are a number of European and American missionary stations. Pop., about 30,000, including over 3000 Armenians. During 1895 it was the scene of fearful atrocities, when about 3000 Armenian Christians were massacred. The ancient town of Malatia or Melitene, 5 miles to the northeast, at Eski-Shehr, now a mass of ruins, was the station of the twelfth legion in the time of Titus and was raised to the rank of a city by Trajan. It was in turn the capital of Armenia Secunda and Armenia Tertia.

MÂLAVIKÂGNIMITRA, mä′lȧ-vė-käg′nė-mė-trȧ. A Sanskrit drama of love and intrigue ascribed to Kalidasa. The leading characters are Agnimitra, King of Vidīsha, and Malavika, an attendant of the Queen. The action is supposed to have taken place during the second century B.C. In poetical quality the work is much inferior to the Sakuntala. It has been translated into German by Albrecht Weber (1856), into French by Foucaux (1877), and into English by Tawney (1875).

MALAYALIM, mä′lȧ-yä′lĭm. Inhabitants of the Malabar coast of southwestern India, sometimes called Malabars. They form one of the civilized peoples of Dravidian stock. They have a written language, the alphabet being derived from Hindu sources. The Malayalam language is thought to have been originally an offshoot of Tamil, but ranks now as an independent tongue, with a literature of its own. Both language and literature, as is the case with all the civilized Dravidian peoples, are being and have been considerably influenced by the modern and old Aryan dialects about them. The Malayalim, who number 6,000,000 or 7,000,000, have been converted to Hinduism, and a few to Christianity. The first great work in Malayalam is the epic *Ramacharita*, dating from the fourteenth century. A collection of 1000 Malayalam proverbs was published at Mangalore in 1868. Consult: R. Caldwell, *Grammar of the Dravidian or South-Indian Family of Languages* (2d ed., London, 1875); R. N. Cust, *Modern Languages of the East Indies* (ib., 1878); L. J. Frohnmeyer, *Progressive Grammar of the Malayalim Language for Europeans* (Mangalore, 1889); T. K. Krishna Menon, "Notes on Malayalam Literature," in *Royal Asiatic Society Journal* (London, 1900). See DRAVIDIANS.

MALAY'AN PEOPLES. An ethnic term, diversely employed by various authorities. Some, who reject the claims of the Malayan or brown race to rank as a separate division of mankind, on the ground that its Asian or Mongolian affinities are both too recent and too apparent, recognize a "Malayic stock," composed of a western or Malayan and an eastern or Polynesian group. (See MALAYO-POLYNESIAN.) By this theory the ancient Malays, presumed to be yellowish brown in complexion, small-statured and short-skulled, are connected with the Indo-Chinese peoples of continental Asia. Others, who also decline to see in the Malayan race one of the primal human stocks, consider the Malay type distinctly Mongoloid. An "Oceanic Mongol group" is postulated which includes all the peoples of Malaysia and the islands of the Pacific who are not Negritos, Papuans, or Indonesians (qq.v.). The population of Malaysia may be divided into four great ethnic groups, Malays, Indonesians, Negritos, and Papuans, while the archipelagoes of the Indian Ocean and the Pacific were peopled by three distinct races, at least one of which has left a linguistic impress upon the Malayans. The Indonesians and Malays do not differ greatly from each other and the former have been regarded by some as proto-Malays. Certain writers, in view of the fact that dolichocephalic head forms occur quite commonly among the existing peoples of the East Indies, restrict the term Indonesian to the dolichocephalic variety of man found in this region. They would apply the term Malay or proto-Malay only to the brachycephalic non-Negrito, non-Papuan, and non-Melanesian variety. According to this theory, before the dispersion over this area of the Orang Malayu, or Malays proper, most of the islands of the Malay Archipelago were inhabited by tribes representing various degrees of intermixture of these two races, while, neglecting migrations from the Asiatic continent, the last 1000 years have witnessed nothing more than similar mixtures in varying degrees. The reasons for separating the so-called Indonesians from the Malayan stock are not, however, convincing. The suggestion of the linguistic unity of the Malayo-Polynesian peoples and recognizing a somatic kinship of all the aborigines of Malaysia, together with the Malays of the Malay Peninsula and the Malays of Madagascar and the natives of Oceanica, except the Negritos, Papuan-Melanesians, and kindred peoples, is now known to rest upon wholly insufficient evidence and has been given up. Besides their use in this broad sense the terms Malay and Malayan are also probably a considerable Malayan or proto-"Malays proper" of the Malay Peninsula, the Menangkabau region of Sumatra, and certain other parts of some of the larger islands, and their representatives scattered in small numbers practically all over the archipelago. There is also probably a considerable Malayan or proto-Malayan element in certain regions of the coast of Farther India, the Chinese littoral, and southern Japan. There may also be a large Malayan element in Japan and even in Korea, due to immigration in the wake of the Kuro-Siwo current from the East Indies, by way of the Philippines, Formosa, and Luchu. Some writers go so far as to attribute the difference between the Chinese and the Japanese largely to the fact of this Malay cross in the latter.

The Malayan peoples present all varieties of savagery, barbarism, and civilization, from the rude tribes of the interior of some of the islands to the more or less cultivated Malays of the coast, the Javanese, and the civilized peoples of the Philippines. The migration which led to the settlement of the Malays in Madagascar, called Malagasy or Hovas, took place apparently before the spread of Hindu influence in the East Indies, to which was in great measure due the religious and political stimulus that created so many kingdoms in Sumatra, Java, with the adjacent smaller islands, and Borneo, and touched even the Philippine Islands on one hand and New Guinea on the other. There have evidently been several waves of proto-Malay and Malay influence in this area. One of the most notable is that which bore the creed of Islam as far as the Moros of the southern Philippine Islands, and raised it upon the ruins of both the Hindu and the Buddhistic faiths in Sumatra and Java. The influence of India in Sumatra seems to have been less than in Java, where exist the remains of the great temple of Boro Buddor (q.v.) and other evidences of Indo-Malay culture. In the little island of Bali a form of Hinduism survives to this day. In parts of Sumatra, Borneo, and Formosa very primitive types of Malayan life and culture are still to be found.

All over the Malayan area the languages of this family show a more or less close kinship with the standard Malay of Menangkabau, which is in many respects the least complicated dialect of the group. The relations of some of the Formosan and Bornean dialects to the Malayan stock are not yet very clear. The Malayo-Polynesian speech family was erected by Bopp on a certain community of vocables which he observed between Malayan and Polynesian languages. Recent examination of richer material than was available for Bopp has shown (Churchill, *The Polynesian Wanderings*, *The Subanu*, etc.) that the sum of this community barely exceeds 250 words, a trivial amount in any vocabulary. This community is now explained as Polynesian loan material which came into the possession of the Malayans during the somewhat protracted period when they were driving the Polynesians out of Indonesia in their own later migration. This linguistic interpretation of events is supported by the fact that between the Malayans and the Polynesians the somatic and cultural differences are irreconcilable with any theory of community of origin. None of the Polynesians proper (except the civilized peoples) possess written alphabets, but among the Malayan peoples a variety of them occur. The Malays proper, like the Philippine Moros, use Arabo-Persian alphabets that came with Islam. Among the civilized peoples of the Philippines, as the Tagals and Visayans, the alphabets in use since the thirteenth century seem to be of Indian origin, and the same statement holds regarding those of certain peoples of Celebes. The Javanese and several of the Sumatran peoples have alphabets of Hindu or Arabic origin. The literary culture of the Malayan peoples is in some sections quite advanced, particularly in Java, where the sacred books are preserved in the Kavi (q.v.) or ancient Javanese language. In Java, too, the puppet show and the primitive drama are at home. The Macassars of Celebes have also developed their literary instinct to a considerable extent. The literature of the civilized tribes of the Philippines is quite large, several thousand books and pamphlets having been printed in the native dialects. The Low Malay of Sumatra has become a sort of *lingua franca* for the whole Malay Archipelago, and has a literature of its own.

Among the Malayans agriculture varies from the rudest tillage of the savage tribes to the highly developed system of the Battas. It is characteristic of the uneven temperament of the Malayan stock that anthropophagy in a curious form (the eating of criminals) lingered so long among a people otherwise so far above the average as the Battas. Head hunting, once common among the wilder tribes in large regions of the archipelago, is dying out, even in Borneo and Formosa. Widespread among Malayan peoples is the custom of betel chewing, the use of the *sumpitan*, or blowgun, and of the *kris*, or dagger. Pile dwellings (see LAKE DWELLINGS) often occur even on dry land. Of interest to the sociologist are the customs of teknonymy, clan-exogamy, patriarchy, and the coexistence of family and individual property. The utilization of iron by the Malayan peoples is one of the marked features of their native culture. Loom weaving forms an important industry, and there has been a development of peculiar dyeing techniques. The extensive use of bamboo and rattan strongly colors Malay culture, particularly in the structural employment of lashings rather than nails for fastening.

The Malayan peoples have shown considerable genius in the direction of art and literature and have produced a number of great men. Some of the native rajahs and sultans of Sumatra and Java have been men of much ability. The Malayans, moreover, are not a decadent or a disappearing race, as the large increases in the population of Java and the Philippines show. Their character has generally been rated rather low by Occidental observers, but the deceit, untrustworthiness, unevenness, treachery, and other bad qualities attributed to them have been much exaggerated and the depth of feeling, honor, and moral and intellectual possibilities correspondingly underestimated.

As to the origin of the Malays, some authorities suppose them to have come from the southeastern part of Asia through the Malay Peninsula, whence they spread over the Indo-Pacific world. According to this theory their first occupation of Sumatra and Java dates from between 1000 and 2000 years before the Christian era, and the expansion of the Malays could not have been much later than the Aryan conquest of India. Others consider the Malays proper to be of comparatively recent origin, and assign their entrance from Malacca upon Indonesia to a period little anterior to the Christian era. The best view is that the Malayan stock is of continental origin and of Mongoloid affinities, developed in certain directions in its insular habitat. The Malayan stock is of very great value to the ethnologist by reason of the numerous and manifold cultures that have influenced it, as Hindu, Chinese, Arab, Portuguese, Dutch, Spanish, English, American, Japanese, from which have resulted important social, religious, political, and linguistic complications. In the northern part of the archipelago intermixture with a primitive Negrito element, Aëtas (see AËTA) of Luzon, has occurred to some extent, while in the east Papuan-Melanesian elements are discernible, and in the central area it is still possible to trace contact zones with such folk as the Toradja of Celebes, the Dusun of Borneo, and the Arafura of Ceram, all of which are considered to be survivals of a race of possibly pygmoid autochthons anterior even to the Polynesian occupation of the islands. Spanish relations with Mexico have caused even some American Indian blood to mingle with that of the natives of part of Mindanao.

MALAYAN SUBREGION. In zoögeography, a faunal district of the Oriental region (q.v.), comprising the Malay Peninsula south of Tenasserim, Sumatra, Java, Borneo, and all the archipelago west and north of Lombok and Celebes, as far as and including the Philippines. It intercalates with the Indian and Chinese subregions along the eastern coast of the Bay of Bengal, and is known in some books as Indo-Malayan. Its southeastern boundary (Wallace's line), at the Strait of Macassar, is curiously distinct from that of the Australian region, although the two are separated only by narrow waters. An explanation of this will be found in the article DISTRIBUTION OF ANIMALS, illustrated by maps. This is almost entirely a region of tropical and forested islands, and its animals are those most typical of the Oriental fauna—i.e., organisms suited to uniform but not extreme heat, plenty of moisture, and approximately uniform meteorological conditions throughout the year. One result of this is an interesting similarity between its faunal characteristics and those of equatorial Africa on the one side and of the Amazonian region on the other. The tapirs and trogons of South America and the African anthropoid apes and hornbills are curiously paralleled by similar Malayan species absent elsewhere. A noteworthy resemblance also exists between the Malayan and Malagasy regions. Two very conspicuous groups characteristic of this subregion are the birds of paradise and the orang-utan—the last recalling the fact that Java was the home of *Pithecanthropus* (q.v.), which, with other considerations, has led many ethnologists to believe that mankind developed its species in this part of the world. See ORIENTAL REGION.

MALAY, mȧ-lā′ *or* mā′lā (INDIAN, or EASTERN), **ARCHIPELAGO.** The largest system of island groups in the world, situated between southeast Asia and the Australian continent, separating the Pacific from the Indian Ocean, and extending 20 degrees north of the equator and about half that distance south of it. Exclusive of New Guinea, the archipelago has a total area of about 745,000 square miles, with an estimated population (1905) of 50,000,000. The principal groups are the Sunda Islands, including Sumatra, Java, Bali, Lombok, Sumbawa, Flores, Timor, and the neighboring islands; Borneo and Celebes, with their dependent isles, to the north of the Sundas; the Philippines, northeast of Borneo, and the Moluccas, east of Celebes. The western, or Dutch, division of New Guinea is also reckoned a part of the Malay Archipelago. The islands are all mountainous, the loftiest peak being Kinabalu in Borneo, 13,698 feet. The archipelago is remarkable for the number of volcanoes, active and extinct. Nearly all of these islands are abundantly watered and covered with luxuriant tropical vegetation. The Portuguese were the first Europeans to engage in trade in the archipelago, but the chief European nations to exploit the islands have been the Dutch and the Spanish, and the archipelago now practically belongs to the former, with the exception of the Philippines (which belong to the United States), the northern part of Borneo (which is British), the British island of Singapore, and a part of the island of Timor (which is Portuguese). The name Indonesia is sometimes applied to the Malay Archipelago.

Foster, in *Hakluyt Society, Works*, series 2, No. 16 (Cambridge, 1905); A. R. Wallace, *Malay Archipelago* (London, 1912).

MALAY′O-POL′YNE′SIAN. A speech family erected by Franz Bopp in 1841 to account for a certain community of vocabulary which he had observed to exist between Malayan and Polynesian languages. This community has now been shown to consist of no more than the mere trifle of some 250 words best explicable as loan material which the Malayans have accumulated from the Polynesians, whom they dislodged. It has been established that the Polynesian languages are of the isolating type and the Malayan languages are agglutinating, therefore they cannot form a single family. The term has now no more than historic interest

MA′LAY (mȧ-lā′ *or* mā′lā) **PENINSULA,** or **MALAC′CA.** A long, narrow peninsula projecting in a southeasterly direction from the southeastern part of Asia, beginning about lat. 13° 30′ N. and terminating in lat. 1° 22′ N. It is bounded by the China Sea on the east and the Indian Ocean on the west, and is separated from Sumatra by the Strait of Malacca (Map: French Indo-China, D 6). It is about 850 miles long and its width varies from 45 miles at the Isthmus of Kra to upward of 200 miles at Perak. The peninsula is formed by the southern extension of the mountain ranges that are the water parting between the basins of the Salwin and Menam rivers. The highest known peak is Gunong Korbu, 7217 feet. The granite and sandstone mountain backbone is not continuous, but is broken into several fragments; and the plains, east and west of the mountains, are cut up into areas, large or small, by broad river valleys, in which comparatively small streams carry the drainage to the sea, some of them being navigable for short distances.

The climate is extremely humid, which makes it disagreeable for foreigners, and the undrained swamps and uncleared jungles offer breeding places for disease-bearing insects. The health conditions of the towns important in commerce have been much improved by sanitary measures. The port of Malacca, e.g., once regarded as the grave of Europeans, is now fairly salubrious. The vegetation is rich and varied, and the forests which still cover nearly the entire peninsula are full of palms, as many as 42 varieties being known to exist. The fauna of the peninsula is not unlike that of Borneo and Sumatra, but it has in addition some species unknown in those islands, as the royal tiger, the elephant, deer, and rhinoceros, of which there are two kinds. The peninsula is very rich in minerals, especially tin, which is mined to a very large extent, the greater part of the world's tin coming from this region. Silver and gold are also found, the export of the latter from the Federated Malay States for 1912 amounting to 14,421 ounces.

The principal agricultural products are raw sugar, cotton, tobacco, coffee, and tea.

Politically the peninsula is divided between Siam and Great Britain. To the former belong the provinces of Quedah, Patani, Kelantan, Trenganu, and some others, occupying the northeastern and middle portions of the peninsula. The southern half of the rich Province of Tenasserim, Burma, forms the northwestern part of the peninsula. The Straits Settlements, consisting of Singapore, Malacca and Penang, with the provinces of Wellesley and the Dingdings, constitute a crown colony of Great Britain, while the Federated Malay States of Perak, Selangor, Negri Sembilan, with its amalgamated states, and Pahang, together with the native state of Johore, are under the protection of Great Britain. The total area of the peninsula is estimated at about 90,000 square miles, with a population of about 2,000,000, consisting for the greater part of Malays and Siamese, with a small number of Negritos, Chinese, and Europeans. The commerce of the peninsula is greatly promoted by the fact that the Strait of Malacca is the gateway between the Far East and the Occident. The vessels of over 50 regular steamship lines are constantly passing through it, stopping at Singapore. For details, see articles on STRAITS SETTLEMENTS; SINGAPORE; PAHANG; PERAK; BURMA; ETC.

MALAYS. The term applied to a particular group or section of the Malayo-Polynesian race, found in its approximate purity in the peninsula bearing this name and the Menangkabau region of Sumatra. Soon after their arrival the Malays proper intermingled to a certain extent with their predecessors. Into the peninsula they brought a relatively high culture. The Malays of the interior are in all respects more fixed in type than those of the coast. With the exception of the degenerate population of the seaports, the Malay gives abundant evidence that he has behind him a somewhat high culture, with which are associated a varied artistic skill and the expressions of a well-developed language and literature. The better part of the Malays, represented by the forest dwellers, as contrasted with the inhabitants of the towns, are not only men well up in their special crafts, but very companionable, and fond of their homes and families. Their loyalty to their native chiefs, their honesty, and their sense of personal honor are marked. See MALAYAN PEOPLES.

MALAY STATES, FEDERATED. See FEDERATED MALAY STATES.

MALBAIE, mȧl'bā'. See MURRAY BAY.

MALBONE, măl-bōn', EDWARD GREENE (1777–1807). An American miniature painter, born at Newport, R. I. In 1800 he accompanied Washington Allston to Charleston, S. C., and the next year went to Europe. At London he met Benjamin West, president of the Royal Society, who recognized his ability and even urged him to make London his permanent residence. Malbone, however, returned to Charleston, and subsequently practiced his art with success in several American cities, devoting himself particularly to miniatures. For sound draftsmanship, grace of execution, and beauty of expression his miniatures bear comparison with those of the great English masters. They are valued possessions of many American private families, and also of the Pennsylvania Academy and of the Boston Museum of Fine Arts, which owns a portrait of Washington Allston. His best canvas is "The Hours," in which the present, past, and future are represented by female figures. This work, which was bought from the Malbone heirs for $1200, is now in the Providence Athenæum.

MALBROOK, mȧl-bru̥k', or **MALBROUGH.** A French satirical song, written about the Duke of Marlborough. It is known also by the words of its first line. The first stanza runs as follows:

> Malbrough s'en va-t-en guerre,
> Mironton, mironton, mirontaine;
> Malbrough s'en va-t-en guerre;
> Ne sait quand reviendra, etc.

The author of the song is unknown, but it was probably written after the battle of Malplaquet (Sept. 11, 1709). It was sung by Marie Antoinette, and it spread from Versailles throughout France. The form of the stanza is similar to that of a lament on the Duke of Guise (1566); but the music cannot be traced back beyond the time of Louis XIV. Beaumarchais incorporated the song in his *Mariage de Figaro* (1784); and Beethoven made use of the melody in his *Battle Symphony.* The tune is well known among English-speaking peoples as that to which the words of "We won't go home till morning" are sung.

MALBROUK (Fr. *malbrouk, malbrouch,* sort of monkey, probably a corruption of Eng. *Marlborough*). A West African monkey (*Cercopithecus cynosurus,* or *Lasiopyga cynosura*), one of the guenons. It has yellowish grizzled fur and a broad flesh-colored face, with a band across the forehead, the stiff side whiskers, throat, and under parts white. Little is known of its habits.

MALCHAM, măl'kăm. See MOLECH.

MALCOLM, măl'kom. The name of four kings of Scotland.—MALCOLM MACDONALD succeeded to the throne on the abdication of Constantine II in 943. The most important event of his reign was the cession of Cumbria about 945 by the English monarch Edmund I. Malcolm was slain about 954 while engaged in quelling a revolt in the north of Scotland.—MALCOLM MACKENNETH was a grandson of the preceding. He ascended the throne in 1005. His life was passed chiefly in repelling the incursions of the Danes. He died in 1034. A collection of laws, the *Leges Malcolmi MacKenneth,* has been attributed to him, but is obviously a work of a later age.—MALCOLM MACDUNCAN, surnamed

Canmore, ascended the throne on the death of Macbeth (q.v.) in 1054, being the son of Duncan, whom Macbeth slew. After William of Normandy had seated himself on the English throne many noble Saxons sought refuge at the Scottish court, among them being Edgar Atheling, nearest of kin to the Confessor, with his mother, Agatha, and his sisters, Margaret and Christina. Margaret, who was young, beautiful, and pious, captivated the heart of the Scottish King, and a marriage quickly followed. Malcolm's new relations, however, unfortunately, embroiled him with the Normans. In 1070 he crossed the border, harried Northumberland and Yorkshire, but was soon obliged to retreat. William the Conqueror retaliated in 1072 and wasted Scotland as far as the Tay. At Abernethy, Malcolm was compelled to acknowledge him as his liege lord, but (as the Scottish historians hold) only for such parts of his dominions as had belonged to England, viz., Cumbria and the Lothians. War was waged between England and Scotland from 1077 to 1080 and broke out again in 1091, probably at the instigation of the fugitive Anglo-Saxons and the discontented Normans, who had been pouring into Scotland during the iron reign of William and had obtained large grants of land from the Scottish monarch. Nothing of note, however, happened, and peace was again concluded; but not long after there was a fresh rupture, and in 1093 Malcolm again crossed the border and laid siege to Alnwick; but while so engaged he was suddenly attacked, defeated, and slain, on Nov. 13, 1093.—MALCOLM, surnamed The Maiden (1141–65), was a grandson of David I, and succeeded that monarch in 1153, when only in his twelfth year. He had no sooner mounted the throne than a Celtic insurrection, headed by Somerled, Lord of the Isles, broke out. Some years after another insurrection broke out among "the wild Scots of Galloway," under their chief, Fergus, to crush which Malcolm had to employ a large force. In 1164 he was obliged to put down a second rebellion, led by Somerled. He died at Jedburgh, of a lingering disease, Dec. 9, 1165.

Bibliography. Robertson, *Scotland under her Early Kings* (Edinburgh, 1862); E. A. Freeman, *Norman Conquest* (5 vols., Oxford, 1867–79); id., *Reign of William Rufus* (2 vols., Oxford, 1882); Skene, *Celtic Scotland* (3 vols., Edinburgh, 1876–80); Andrew Lang, *History of Scotland*, vol. i (New York, 1900); A. C. Lawrie, *Annals of the Reigns of Malcolm and William, Kings of Scotland* (ib., 1911).

MALCOLM, SIR GEORGE (1818–97). A British general, born at Bombay, India. He entered the army at 18, and three years later was taking part in the Afghan War as deputy assistant to the commissary general. He was promoted to be a lieutenant in 1840, captain in 1849, and lieutenant colonel in 1854, having served in Baluchistan and throughout the second Sikh War. His next campaign was in Persia (1856–57). He was made colonel (1860) and major general (1867) for his gallant services during the Indian Mutiny, and after the Abyssinian War of 1868 was knighted, made lieutenant general (1875), general (1877), and publicly thanked by Parliament. He retired in 1881. His *Remarks on the Indian Army* (1868), published privately, gained importance from the fact of his having commanded Sind cavalry and Bombay native infantry.

MALCOLM, SIR JOHN (1769–1833). A British colonial administrator and author. He was born at Burnfoot, Dumfriesshire, Scotland, May 2, 1769, and at the age of 14 went to India as a cadet in the Madras army. He distinguished himself at the siege of Seringapatam in 1792 and was appointed to the staff as Persian interpreter. In 1800 he was sent as Envoy to Persia, to form an alliance with that country against Bonaparte, in which he succeeded. In 1808 and 1810 he was sent as Minister Plenipotentiary to the Persian court. In 1803 he had been appointed Governor of Mysore; and during the two following years his administrative talents were of important service to the government in deducing to order and tranquillity the newly conquered Mahratta states. In 1812 he returned to England, received the honor of knighthood, and after five years returned to India as the Governor-General's political agent in the Deccan, with the rank of brigadier general in the Indian army; in the latter capacity he distinguished himself in the wars against the Pindarris and Holkar. He was in England again from 1821 to 1827, when he was appointed Governor of Bombay. He finally left India in 1830 and died of paralysis at Windsor, May 30, 1833. Malcolm's writings are: *Sketch of the Sikhs* (1812); *A History of Persia* (London, 1815; 2d ed., 1828); *Memoir of Central India* (ib., 1823); *Political History of India from 1784 to 1823* (ib., 1826); *Life of Lord Clive* (ib., 1836), a posthumous work. Consult J. W. Kaye, *The Life and Correspondence of Major-General Sir John Malcolm* (2 vols., ib., 1856).

MALCZEWSKI, mȧl′chĕv′skė, or **MALCZESKI,** ANTONI (1792–1826). A Polish poet, who was born and died at Warsaw. In 1811 he entered the Polish army and led a gay life in Warsaw, but resigned in 1816, after being seriously wounded in a duel. He went abroad, and in Venice became intimate with Byron, whose *Mazeppa* was directly inspired by Malczewski's vivid account of the story. He returned to Warsaw, then settled in Volhynia, where he wrote *Marja* (1825). The plot is simple. Vaclav, a nobleman, is united to Marja against his father's will. The latter feigns reconciliation and sends out his son to fight the Tatars. In his son's absence he causes Marja to be drowned and Vaclav finds her corpse on his return. Malczewski fell in love with the wife of a friend and had to leave for Warsaw, whither she soon followed him, and where they lived in misery. The pictures of the steppes, the portrayals of passion, the characterization of the chief personages of *Marja* are gems. The poem appeared in a German translation by Nitschmann in his *Polnischer Parnass* (4th ed., Leipzig, 1875).

MAL DE MER, mȧl de mâr′. See SEASICKNESS.

MALDEN, mạl′den. A city, including several villages, in Middlesex Co., Mass., 5 miles north of Boston, on the Malden River and on the Boston and Maine Railroad (Map: Massachusetts, E 3). It has a public library, a city hospital, a Home for Aged Persons, and a Young Men's Christian Association building. There are extensive rubber interests and manufactories of boots and shoes, cotton goods, fibre goods, wire cord, sweaters and jerseys, leather, and boot and shoe lasts. The city also enjoys some reputation as a residential place. Malden's total expenditures in 1912–13 were $2,120,000, the principal items of expense being $245,000 for schools, $32,000 for the water works, $33,000 for charitable institutions, $57,000 for the fire department, $51,000 for the police department, and $61,000 for sanitation. The city's income was $2,170,000. The water works, which supply Malden and the cities of Medford and Melrose, were built in 1869 at a cost of over $1,000,000. These works are now a part of the Metropolitan District water system. Pop., 1890, 23,031; 1900, 33,664; 1910, 44,404; 1914 (U. S. est.), 48,979; 1920, 49,103.

Malden formed part of Charlestown until 1649, when it was incorporated as a separate town. Michael Wigglesworth (q.v.) was an early pastor here, where in 1662 he wrote *The Day of Doom.* In 1881 the town was incorporated as a city. Consult Corey, *The History of Malden, Massachusetts* (Malden, 1899).

MALDIVE (măl′dīv) **ISLANDS.** A chain of low coral islands in the Indian Ocean, about 300 miles southwest of Cape Comorin (Map: Asia, J 8). It consists of 17 compound atolls, each of which has a number of smaller atolls arranged around a central lagoon, so that the entire number of islets amounts to many hundred, the aggregate area being, however, only about 200 square miles. The elevation above the sea level is in no case more than 20 feet, and generally only 6 feet. The larger and inhabited islands, of which there are about 200, are covered with coconut palms and fig, citron, and breadfruit trees; wild fowl and fish are abundant. The climate is very hot and, owing to the numerous lagoons and swamps, unhealthful. The inhabitants, who number about 50,000, are Singhalese of the Mohammedan faith and are good sailors, carrying on an active trade with the Malabar coast, to which they export in their own vessels coconuts, copra, tortoise shells, and dried bonito fish. They are governed by a sultan residing at Mali, the largest of the atolls, but are under British protection and subject to the Governor of Ceylon. They were formerly under the Portuguese and the Dutch flag. Consult J. S. Gardiner (ed.), *Fauna and Geography of Maldive and Laccadive Archipelagoes; being the Account of the Work and Collections Made during 1899 and 1900* (10 vols., Cambridge, 1901–06); Alexander Agassiz, "The Coral Reefs of the Maldives," in *Harvard University, Museum of Comparative Zoölogy, Memoirs,* vol. xxix (Cambridge, Mass., 1903).

MALDIVE LANGUAGE. The Indian dialect spoken in the Maldive Islands. It is closely related to the Ceylonese (see CEYLON, *Language and Literature*) and represents a younger stage of it. The phonological tendencies already seen in Ceylonese have been carried further in Maldive, and it seems that the latter dialect has been influenced by some non-Indian language, yet its Ceylonese origin is clear. The Maldive alphabet was formerly written from left to right, like the Ceylonese script, on which it seems to have been based. Later the direction was reversed, and to the 24 original letters three from the Perso-Arabic alphabet were added. No literature exists as yet, and before the researches of Wilhelm Geiger, who visited the islands for linguistic investigations in 1895–96, the only written specimens of Maldive were the vocabularies of Pyrard (1602–07) and Christopher (1834), as well as a small manuscript dictionary at Copenhagen and a glossed Persian-Hindustani dictionary in the India Office in London. In 1902 Geiger issued an *Etymological Vocabulary of the Mâldivian Language* (London). Consult also the same author's *Maldivische Studien* (Munich, 1900–02).

MALDON, mạl′don. A market town and river port in Essex, England, a mile below the confluence of the Chelmer and the Blackwater, 9 miles east of Chelmsford (Map: England, G 5). It has manufactures of crystallized salt, also brickmaking, iron founding, oyster fisheries, and some shipping trade. It has a quaint town or moot hall built in the reign of Henry VI and a grammar school founded in 1547. At Osea Island, off the town, is a farm colony for the London unemployed. It has Roman, Saxon, and Danish remains and is mentioned in 913 as an encampment of Edward the Elder. It received its first charter from Henry II and was incorporated in 1553. Pop., 1901, 5600; 1911, 6253. Near Maldon is Purleigh, where Lawrence Washington, great-grandfather of George Washington, was rector from 1632 till expelled by the Puritans in 1642. The fine tower of this church has been restored by Americans as a Washington memorial.

MAL′DONA′TUS, or **MALDONADO,** JOHANNES (1533–83). A Jesuit theologian. He was born at Casas de Reina, Estremadura, Spain, and was educated at Salamanca. There he became professor of theology (1556); in 1562 he became a Jesuit at Rome and in 1563 was sent to Paris to found a college. He taught with such success that jealousy caused charges of heresy against him by the Sorbonne. He was cleared of heresy in 1575, but withdrew to Bourges and ultimately (1580) to Rome, where he died, Jan. 5, 1583. He is reckoned one of the greatest Roman Catholic exegetes. A list of his books is in Backer, *Bibliothèque des écrivains de la compagnie de Jésus* (Paris, 1890–1900). Most famous of them is his commentary on the Gospels, of which the best edition is by Raich (Mainz. 1874); English translation by Davis (2d ed., London, 1888). Consult the preface to Raich's edition; also Prat, *Maldonat et l'Université de Paris au XVIe siècle* (Paris, 1856).

MALEBRANCHE, mȧl′bräNsh′, NICOLAS (1638–1715). A French philosopher. He was born in Paris, where his father was president of the Chambre des Comptes. He was deformed and sickly, with a constitutional inclination to solitude. His early education was conducted at home. After studying theology at the Sorbonne, he entered the Congregation of the Oratory at the age of 22. He devoted himself without much success to critical and historical studies, until Descartes' *Traité de l'homme* fell into his hands and opened up to him his life work. He spent 10 years in the study of the Cartesian system of philosophy and published the results in his famous *Recherche de la vérité* (1674; Eng. trans., by T. Taylor, London, 1694). This work, admirably written, had for its object the investigation of the causes of the errors to which the human mind is liable, as well as of the nature of truth and the way of reaching it. To condense its theory: God, by reason of His omnipotence, is able to give an external existence to His thoughts; in this consists creation. The material world is an inexplicable duplication of God's ideas and is by God known through His ideas. We human beings know this material world by seeing His ideas of it. Unless we saw God "we could see nothing else," and in seeing God we see His ideas, which are the prototype of the material world. God is the cause of all changes taking place in bodies and in souls, the latter being therefore merely passive in the former. All apparent causation of object by object in the perceived world is only occasional causation. (See OCCASIONALISM.) All physical and psychical changes follow an apparent causal order only because God uses the occurrence of a so-called cause as the occasion on which He calls into being a so-called effect. Only God can cause events to happen; it is an incommunicable divine attribute.

Malebranche's system is a kind of mystic idealism, in some important respects anticipating Berkeley's (q.v.) idealism, but approximating pantheism much more than Berkeley's theory. It was subjected to a thorough examination by Locke and Leibnitz and opposed by Bossuet and especially by Antoine Arnauld, the Jansenist leader. The attacks made upon it led Malebranche to discuss the relations between philosophy and theology in *Conversations métaphysiques et chrétiennes* (1677; Eng. trans., London, 1698), which was followed by a *Traité de la nature et de la grâce* (1680; Eng. trans., London, 1695) and by *Méditations chrétiennes et métaphysiques* (1683), while he dealt with his chief antagonist expressly in a series of *Réponses de Malebranche à Arnauld.* Still further volumes written in similar spirit were *Traité de morale* (1684; Eng. trans., 1699), *Entretiens sur le métaphysique et sur la religion* (1688), *Traité de l'amour de Dieu* (1697), *Entretiens d'un philosophe chrétien et d'un philosophe chinois sur l'existence et la nature de Dieu* (1708), and *Réflexions sur la prémotion physique* (1715). Malebranche died in Paris. There his collected works were published in 1712 and again in 1837 and 1859–71. Consult, for his life, André, *Vie du R. P. Malebranche* (Paris, 1886); and for his philosophy: Blampignon, *Etude sur Malebranche d'après des documents manuscrits* (ib., 1862); Ollé-Laprune, *La philosophie de Malebranche* (ib., 1870–72); Grimm, "Malebranches Erkenntnistheorie und deren Verhältnis zur Erkenntnistheorie des Descartes," in *Zeitschrift für Philosophie und philosophische Kritik* (Berlin, 1877); Joly, *Malebranche* (Paris, 1901); G. N. Dolson, "The Idealism of Malebranche," in the *Philosophical Review*, vol. xv (New York, 1906); Lewin, *Der Lehren von den Ideen bei Malebranche* (Halle, 1912).

MAL′ECITE. An Algonquian tribe, closely related to the Abnaki and scattered over western New Brunswick, chiefly along the St. John River, to the number of about 850. The name, frequently written Malisit, has been variously rendered "disfigured foot" and "broken talkers." Together with the more eastern bands of the Abnaki, they were sometimes known as Etchemin. In the Colonial wars they took the French side.

MALECKI, mȧ-lĕt′skė̂, ANTONI (1821–1913). A Polish poet, philologist, historian, and scientist. He was born near Posen, studied philology and history at Berlin, and afterward was instructor in classical philology at Cracow and Innsbruck. From 1856 until 1873 he was professor of Polish language and literature at the University of Lemberg. He became a member of the Austrian House of Peers in 1881. Through his scientific writings he was widely known in Poland, particularly after the publication of his two Polish grammars, *Gramatyka języka polskiego większa* (1863) and *Gramatyka historyczno-porownawcza języka polskiego* (2 vols., 1879)—the best Polish grammar. His ability as a literary critic and biographer is shown in his study of the poet Slowacki, *Juliusz Slowacki, jego życie i dziela* (3 vols., 1866–67). He wrote also *List żelazny* (1854; in German, 1858), an historical drama; *Grochowy wieniec* (1855), a comedy; *Jadwirga* (1860), a tragedy. Among other things showing his philological scholarship and classical interests are his *Encyklopedya filologii Klasycznej* (1851) and the translations of Sophocles' *Elektra* and *Antigone* (1854). He was a member of several learned societies, took an active part in the political life of Galicia, and was to the end of his life curator of the Ossolinsk National Institute at Lemberg.

MALE FERN (*Aspidium filix-mas*). See LADY FERN.

MALEIC (mȧ-lē′ĭk) **ACID.** See FUMARIC AND MALEIC ACIDS.

MALEO, măl′ė̂-ō, **MAL′LEE BIRD.** The mound bird (q.v.) of Celebes.

MALESHERBES, mȧl′zârb′, CHRÉTIEN GUILLAUME DE LAMOIGNON DE (1721–94). A distinguished French statesman, born at Paris and educated at the Jesuit College of Paris. He became counselor to the Parlement of Paris in 1745 and succeeded his father as president of the Court of Aids in 1750. In this office and as censor of the press he was an outspoken champion of the liberties of the people against the monarchy. By him in great measure the publication of the famous *Encyclopédie* was made possible. In 1771 his bold remonstrances against the abuses of law which Louis XV was perpetrating led to his banishment to one of his estates. Louis XVI, who esteemed him, recalled Malesherbes in 1774. In 1775 he was appointed Minister of the Interior, his friend Turgot being at this time Minister of Finance; but in 1776 he resigned, his attempts at internal reform having proven unsuccessful against the intrigues of privileged interests. From this period to the Revolution he passed his time in travel or in the improvement of his estates, with the exception of one year (1787–88) when he was a Minister of State. Malesherbes took no part in the early movements of the Revolution, but in 1792 came forward and obtained permission from the Convention to conduct the defense of Louis XVI. He helped his old master little and caused his own ruin. Arrested in December, 1793, he was found guilty of treason and executed with several members of his family in April, 1794. Malesherbes was a member of the French Academy, a writer of great ability on political, legal, and financial questions, and one of the most virtuous and high-minded statesmen of the eighteenth century.

Bibliography. Various writings of Malesherbes have been published in *Œuvres choisies de Malesherbes* (Paris, 1809); Gaillard, *Eloge historique* (ib., 1805); Dubois, *Notice historique* (ib., 1806); J. B. C. Isoard (called Delisle de Sales), *Life of Lamoignon Malesherbes*, translated by Edward Mangin (2d ed., Bath, England, 1814); F. A. de Boissy d'Anglais, *Essai sur la vie, les écrits, les opinions de M. de Malesherbes* (Paris, 1818); Marquis de Beaucourt, *Captivité et dernières heures de Louis XVI* (ib., 1892); Vieux, *Les Lamoignons, une vieille famille de robe* (ib., 1896).

MALET, mȧ′lā′, CLAUDE FRANÇOIS DE (1754–1812). A conspirator against Napoleon I. He was born at Dôle, in the Department of Jura, and in 1770 joined the King's musketeers. On the outbreak of the Revolution he joined the National Guard and fought in 1792 on the Rhine. Subsequently he saw service in Italy, attaining the rank of brigadier general in 1799. From the establishment of the Consulate he came to regard Napoleon's motives with suspicion and by his open advocacy of republican institutions aroused the ill will of Napoleon. In 1808 he was charged with conspiracy and thrown into prison, where, in conjunction with other suspects, he busied himself with hatching plans for the overthrow of the Emperor. Napoleon's absence during the Russian expedition (1812) seemed to offer the long-awaited opportunity. Malet escaped from prison and, by spreading a report of Napoleon's death in Russia, succeeded in gaining over two regiments of the Napoleon Guard. After liberating two of his comrades in prison, Generals Guidal and Lahorie, he attempted to win over Hullin, commandant of Paris, but failed, and, attempting force, was overpowered. The following day Malet, Lahorie, and Guidal were brought before a court-martial and condemned to death, and on October 29 they were executed. Consult Hamel, *Histoire des deux conspirations du général Malet* (Paris, 1873).

MAL'ET, Lucas. An English novelist. See Harrison, Mary Saint Leger.

MALFATTI, mȧl-fȧt'tē, Giovanni Francesco Giuseppe (1731–1807). An Italian mathematician, born at Ala di Trento. His early education was begun at Trento, but at the age of 12 he was sent to Verona, where he entered a college. There he showed such remarkable mathematical ability that he was invited to Bologna at the age of 17, where he carried on his studies at the university, coming under the influence of Riccati in mathematics and Bassi in physics. In 1771 he was made professor of higher mathematics at Ferrara, a position which he filled for about 30 years. Malfatti is chiefly known to-day for an interesting problem which he proposed in a memoir published in 1803, and of which he gave the first solution. The problem is as follows: in a triangular prism to inscribe three cylinders of altitude equal to that of the prism and of maximum volume, so that the remaining volume of the prism shall be a minimum. The problem reduces to the simpler one: to inscribe in a given triangle three circles each tangent to the other two and to two sides of the triangle. It is a curious fact that the same problem was given by the Japanese mathematician Ban Seiyei in 1781 with an algebraic and involved solution. A simpler solution was given by Ajima Chokuyen (1739–98) a little later. For an isosceles triangle the problem appears in the *Opera* of Jakob Bernoulli (Geneva, 1744). The history of the problem has been written several times. Consult: Wittstein, *Geschichte der Malfattischen Problems* (Munich, 1817); Boncompagni, *Bullettino di bibliografia e di storia delle scienze matematiche e fisiche*, vol. ix (Rome, 1876); also Baker, "The History of Malfatti's Problem," in the *Bulletin of the Philosophical Society of Washington*, vol. ii (Washington, 1874).

MALFEA'SANCE (Fr. *malfaisance*, evildoing, from *malfaisant*, doing evil, from *mal*, from Lat. *malus*, bad + *faisant*, pres. p. of *faire*, from Lat. *facere*, to do). The doing of an unlawful act. It is distinguished by the fact that it consists in a positive and active breach of duty from *misfeasance*, which is the performance of a duty in an unlawful or improper manner, especially in a culpably negligent manner, and from *nonfeasance*, which is the total omission to perform an act which one is under a duty to perform. An agent or servant is always personally liable for malfeasance, although the unlawful act has been commanded or ratified by the principal or master. It is often provided by statute that malfeasance in office shall subject the offender to removal from office or other position of trust or even to criminal prosecution. In such connection the term has been uniformly interpreted as involving the idea of evildoing, of conscious transgression of legal duty. An administrator or executor, a guardian, a trustee of a private fund, or a director of a corporation, or any person in like position, is guilty of malfeasance when he wrongfully diverts the assets of the estate or the corporation, or when he mingles them with his own funds and uses them for his own purposes. See Misfeasance; Nonfeasance; Tort; and consult the authorities referred to under Criminal Law; Tort; Trust; etc.

MAL'FORMA'TION (from Lat. *malus*, bad + *formatio*, formation, from *formare*, to shape, from *forma*, shape). The abnormal process which gives rise to an organ or a whole plant whose form is strikingly different from the ordinary; by metonymy, the organ or plant itself, also called a monstrosity. The term "malformation" is applied most properly to a grotesque form, and particularly to one in which the departure from the normal is apparently unrelated to its function. The term "cecidium" has been proposed to include galls and malformations, the cause being indicated by prefixes. That branch of biological science which deals with malformations is known as teratology.

The distinction between malformations and variations is wholly arbitrary. Almost all cultivated plants have been brought to their present state of perfection by cumulative selection, the desired variations being fixed by proper breeding until a race has been developed. The organs in these cultivated races, however, differ from those of the wild original oftentimes far more than do those aberrant forms which are called malformations. The one, however, has arisen slowly by gradations; the other has appeared suddenly. Suddenness of origin, therefore, is one of the criteria of malformation. Malformations may be due to any local disturbance of the usual course of growth and development; e.g., local or general disease. Local disease is often produced by the presence of either an animal or a plant parasite, which produces malformations known as galls. Other malformations are due either to the action of external conditions, such as light and moisture, or to causes which, being entirely unknown, are assumed to be internal. Little has as yet been done in the experimental study of malformations, but since plant organs are remarkably plastic, it is scarcely to be doubted that the specific action of external agents will yet be demonstrated. In very few cases, however, can explanation of the origin of malformations be given at present. There is no question that, having once occurred, malformations may be transmitted to the offspring. Horticulturists are familiar with many instances of this. Malformations are known in all groups of plants, especially among the larger ferns and seed plants. Nearly 4000 species in these two groups have produced monstrosities which have been described. Only a few of the more important classes of deviation from the normal can be mentioned.

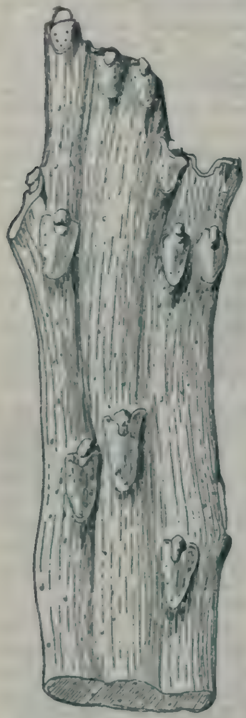

FIG. 1. FASCIATED SHOOT OF AILANTHUS. (AFTER BAILEY.)

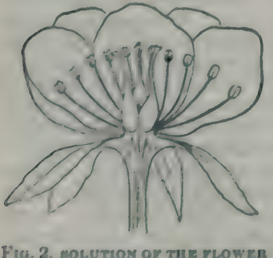

FIG. 2. SOLUTION OF THE FLOWER PARTS.

Longitudinal section of apple blossom. The calyx, petals, and stamens are normally closely united into a mass about the pistils. Here each set is distinct.

1. *Suppression.*—For unknown reasons organs may entirely fail to appear, or they may be arrested in a very young state, so that they do not become evident, or they may be dwarfed by stoppage of growth when partially developed. All possible gradations occur between organs of normal size and those that are completely suppressed. 2. *Hypertrophy.* — From equally unknown causes an organ may develop to an extraordinary size without undergoing any noteworthy change in form. It is common to ascribe hypertrophy to an excessive supply of food, but other stimuli must certainly operate. Young shoots of heavily pruned trees or suckers from the stems often have all organs immensely enlarged. 3. *Concrescence* is a term applied to the actual union of parts in the course of their development. Such unions are not common, most of the cases of apparent union being explicable in an entirely different fashion. Thus the apparent union of flower parts is due to the growth of a ring of tissue underneath the developing separate rudiments, carrying these upward on the edge of a growing cup or cylinder. (See FLOWER.) Actual union is due to the adhesion of young surface cells of organs which are closely crowded as they are forming. The union is seldom firm, and slight pressure suffices to separate the adherent parts without tearing. 4. *Fasciation.* — Stems, normally cylindrical, sometimes develop in a flattened form, several to many times the ordinary diameter in one direction and not unusually thickened in the other. (Fig. 1.) Not infrequently one edge of this broad stem grows more rapidly than the other, when it becomes curved edgewise, crosier-like. The ridges and grooves on the surface suggest the union of several normal stems. Contrary to appearance, however, such stems are not ordinarily due to congenital union of independent stems, each from a single bud, but are produced by the simultaneous development of several buds in line. Fasciation is very common in rapidly growing stems, which are abundantly supplied with food and water. The young shoots of asparagus, the flower stalks (scapes) of the dandelion, and young shoots from severely pruned trees frequently furnish fine examples. 5. *Solution.*—In most seed plants some of the foliar or floral structures are ordinarily developed in circles or whorls or in a crowded spiral. If nowhere else, this is certain to occur in the flowers. (Fig. 2.) Sometimes the stem develops between the points of attachment of these normally crowded leaves, separating them unusually. Thus it comes that flower leaves are sometimes separated by considerable lengths of stem, and the flower loses its characteristic form. Not infrequently at the same time the petals lose their brighter hues and become greenish. 6. *Proliferation* is a continued growth of an axis whose growth is normally finished, or the development of a branch from growing points which ordinarily either are not formed at all or remain dormant. Thus, the formation of a flower usually checks the terminal growth of the axis on which it occurs, but in the pear and apple it not infre-

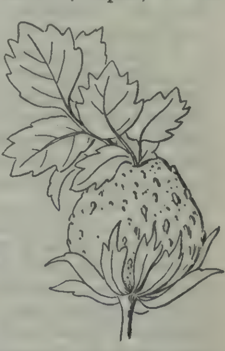

FIG. 3. PROLIFERATION.

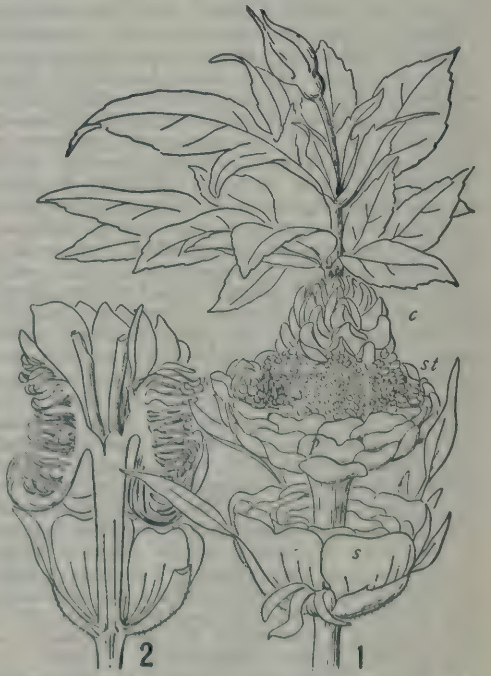
Strawberry with axis normally stopped by flower prolonged into a leafy shoot after fruiting.



2. Longitudinal section. 1. External view.

FIG. 4. PROLIFEROUS ROSE.

The "hip" is absent; sepals, *s*, leaflike; petals, *p*, unaffected; above them a circle, *st*, of miniature roses with numerous petals, stamens, etc.; *c*, scales in many rows; above those a whorl of five foliage leaves. The axis is prolonged above the calyx and beyond the scales, carrying foliage leaves and a flower bud.

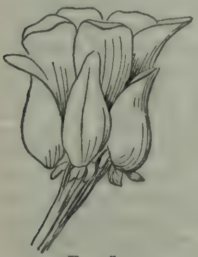


Fig. 5.

Regular peloria of violet, five-spurred sepals replacing the normally single one.

quently resumes its growth after the fruit has begun to form and develops a leafy twig beyond it. (Fig. 3.) In a similar way a flower cluster, such as the head in asters and sunflowers, ordinarily checks the growth of the axis, but occasionally it is prolonged through the cluster, leaving it surrounding the stem. While branches ordinarily occur in the axils of foliage leaves, they do not usually develop in the axils of floral leaves. This may occur, however, and a short branch bearing a complete flower may arise in the axil of each petal or sepal. (Fig. 4.) Some double flowers are made extra-double by this sort of proliferation. A form of proliferation in the flower, when the branches show a tendency to separate readily from the parent, to develop roots, or to become bulblike and reproduce the plant readily, is called vivipary (q.v.). 7. *Torsion.*—Stems normally straight or leaves normally flat may, through more extensive growth of one part or another, be twisted or crinkled.

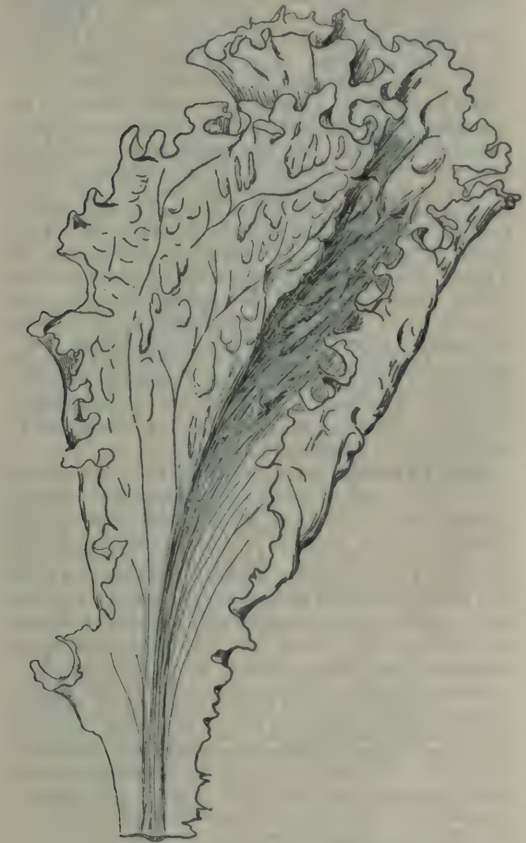

Fig. 6. crispate leaf of lettuce.

Lettuce leaves show a crispate form on a large scale (Fig. 6), and twisted stems are extremely common. 8. *Abnormal branching* of leaves is not infrequent. Clover leaves, normally with three leaflets (branches), are often found with four or five, or even as many as seven. The leaves of the dahlia, hickory (Fig. 7), and many other plants show similar deviations from the normal. Abnormally repeated branching in flower clusters is also common. (Fig. 8.) 9. *Peloria.*—Irregular flowers, i.e., those in which some parts are larger or of a different shape from the others, sometimes develop all the parts of like form and size. Thus the yellow and orange flower of butter and eggs or toadflax has usually one spurred petal; but not infrequently all five of the petals become spurred, and the flower is then radially symmetrical. (Fig. 5.) A similar but reverse change occurs when flowers which are radially symmetrical become unsymmetrical, as when the tubular ray flowers of the wild chrysanthemum or aster develop ligulate corollas. This is quite as monstrous a form as the opposite, but has not been included among malformations.

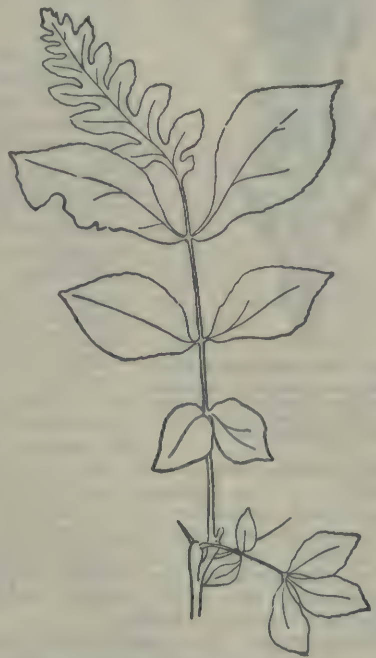

Fig. 7. leaf of hickory.

Showing abnormally branched terminal leaflet.

10. *Transformation* of floral parts is extremely common. Thus, sepals, normally green, may grow into petal-like form and color; while petals may take the shape and function of stamens and pistils. Transformation of this sort, i.e., from a less specialized into a more specialized organ, is not so frequent, and the organs are usually very imperfect. Transformation in the other direction, i.e., from specialized to less specialized organs, is so common that they are scarcely thought of as malformations. Thus, pistils and stamens may develop as petals, a transformation which occurs in most double flowers; petals may be transformed into sepals, or even into imperfect foliage leaves. Indeed, all parts of the flower may be developed as irregular green leaves, of which the so-called green roses are a widely known instance. 11. *Pleimomery,* i.e., increase in the number of any group of or-

gans, occurs most commonly in the floral regions. Some double flowers owe their origin purely to this phenomenon. The increase may affect the number of parts in a whorl or the number of whorls. In the Bahía or navel orange an additional number of carpels is regularly produced, and an imperfect fruit develops, inclosed by the larger one. The so-called two-story apples have their origin in a similar change. Occasionally the additional carpels are lateral to the others, in which case an imperfect fruit may be developed alongside the more perfect one.

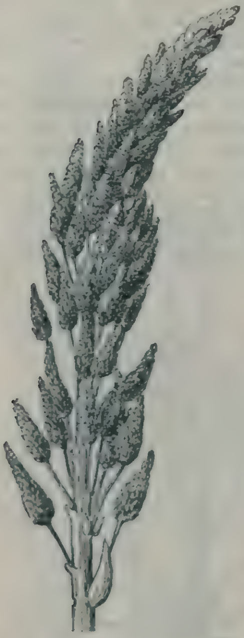

FIG. 8. ABNORMAL BRANCHING.

The flower cluster of plantain abnormally branched; the normal inflorescence is formed of crowded single flowers.

Malformations differ strikingly from galls in the process of their formation, which is due to intrinsic causes, whereas galls result from some extrinsic cause such as the presence in the plant tissues of insects, mites, worms, fungi, slime molds, etc., or from the secretions of these creatures, or from the presence of both organisms and secretions. Like malformations, galls may appear upon the roots, stems, leaves, or flowers and may present very diverse abnormalities, particularly as to their external form and to the peculiar and special tissues which compose them.

Bibliography. The most important works are the following: Moquin Tandon, *Eléments de tératologie végétale* (Paris, 1841); Masters, *Vegetable Teratology* (London, 1869); Penzig, *Pflanzenteratologie* (Genoa, 1890–94), in which the extensive literature up to its date is cited. See GALLS. For malformations in human anatomy and physiology, see DEFORMITIES; MONSTROSITY.

MALHERBE, má′lârb′, FRANÇOIS DE (1555–1628). A French poet and critic, born at Caen. Though Malherbe himself wrote very little poetry of any value, he did much to imbue his contemporaries with a critical sense. Malherbe came after the individualism of the Renaissance had spent its originality. Intellectual lassitude found its expression in criticism, and this found its natural voice in Malherbe, who expressed exactly the state of mind of the cultured men of his time and heralded all that is typical in the literature of the age of Louis XIV, though he was far from typical of its varied genius. With him the temper of mind that prefers order and rule to originality and individuality began to dominate French literature. This temper is represented by Malherbe rather than caused by him. His *Works* (1630), besides translations and correspondence of much historic interest, consist of 125 poems and a *Commentaire sur Desportes*. The only poem that survives in popular memory is the rather frosty *Ode of Consolation* to his friend Du Perrier on the loss of his daughter. Malherbe had a cosmopolitan training in Normandy, Paris, Heidelberg, and Basel and enjoyed court patronage through life. It was this that gave authority to his linguistic and rhetorical dicta, which helped essentially to make the French of Paris the standard for France and to give French thinkers the ideal of logical precision and clarity that has since been their enduring characteristic. His exaggeration of the value of correct diction and prosody was at the time a necessary protest against the careless negligence of genius, though his ideas were carried to excess by his critical successors, of whom the chief was Boileau (q.v.). Malherbe, though he loved to be called a tyrant of words, was a student of popular phraseology, even to the language of the markets, and took thence, as he did from his poetic predecessors, whom also he affected to depise, what he found to his purpose. His *Works*, first collected in 1630, were reëdited in 1666, 1757, 1842, and best by Lalanne (5 vols., Paris, 1860–65). These editions contain the *Life* by Racan, Malherbe's contemporary and pupil. Among the more recent studies of Malherbe may be named Gasté, *La jeunesse de Malherbe* (Paris, 1890); Brunot, *La doctrine de Malherbe* (ib., 1891); Allais, *Malherbe et la poésie française* (ib., 1892); Arnould, *Anecdotes inédites sur Malherbe* (ib., 1892); Bourrienne, *Malherbe* (ib., 1893); id., *Points obscurs et nouveaux de la vie de Malherbe* (ib., 1895); Duc de Broglie, *Malherbe* (ib., 1897).

MALI, mä′lė̄, CHRISTIAN (1832–1906). A German painter, born at Broekhuizen, near Utrecht, Holland. He was early taken to Württemberg, where he practiced wood carving. After his removal to Munich in 1857 he took up landscape painting. A visit to Italy suggested architectural subjects, and studies in Düsseldorf and Paris, where he was influenced by the works of Troyon, led him to the production of pictures in which animals formed the prominent feature. Specimens of these various phases are a "View in Verona" (1866) and "Bavarian Alpine Pasture" (1890), both in the New Pinakothek at Munich; "Shepherd's Morning Greeting," in the Stuttgart Gallery; "Sheep in an Approaching Storm"; "Morning near Amalfi." He received a gold medal in London in 1876.

MALIBRAN, má′lė̄′bräɴ′, MARIA FELICITA (1808–36). A French mezzo-soprano opera singer, born in Paris. She was the daughter of Manuel García (1775–1832), the famous Spanish teacher of singing. At the early age of seven she was a pupil of the famous Panseron; at 15 she became a pupil of her father and two years later made an extraordinarily successful début in London, after which her father attempted to establish the Italian opera in New York, but without success. There she married M. Malibran, a Frenchman. After her husband's failure in business she returned to the stage and was received with great enthusiasm in France, England, Germany, and Italy. Her first marriage having been dissolved, she married De Bériot, the famous violinist, in 1836; but in September of that year she died at Manchester, whither she had gone to take part in a musical festival. Malibran was a woman of generous impulses and magnetic personality, which, coupled with a voice of unusual range and flexibility, served to make her one of the most popular and successful prima donnas of modern times. Consult: I. Nathan, *Life of Mme. Maria Malibran de Bériot* (London, 1846); Arthur Pougin, *Marie Malibran, histoire d'une cantatrice* (Paris, 1911; Eng. trans., London, 1911); *Clément Languine, La Malibran* (Paris, 1911).

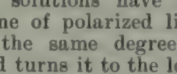
MALIC (mā'lĭk) **ACID,** $C_4H_6O_5$. An organic substance of which two modifications are theoretically capable of existence. The two possess the same chemical properties and differ from each other only in one of their optical properties, viz., the direction in which they rotate the plane of polarized light.

1. The modification of malic acid that is usually met with is found widely distributed in the plant world. The name malic is derived from the Latin *malum*, an apple, the acid having been first discovered by Scheele in unripe apples (1785); but the acid occurs also, either in the free state or combined in the form of salts (*malates*), in gooseberries, currants—in fact, in most acidulous fruits. It may be readily prepared by boiling the expressed juice of unripe mountain-ash berries with milk of lime and dissolving the precipitated neutral calcium salt in hot nitric acid diluted with water; the acid calcium salt thus produced is decomposed with oxalic acid, the precipitated calcium oxalate removed by filtration, and the filtrated solution of malic acid evaporated to dryness. In this manner malic acid may be obtained in the form of colorless, deliquescent crystals that melt at 100° C. (212° F.) and are readily soluble in water and in alcohol. The solutions have the power of turning the plane of polarized light to the left. If kept for a considerable time at a temperature of about 150° C. (302° F.), malic acid loses the elements of water and is largely transformed into fumaric acid (q.v.).

2. The second modification of malic acid may be obtained by the reduction of ordinary tartaric acid. It also occurs, though rarely, in nature. Its solutions have the power of turning the plane of polarized light to the right, and that to the same degree to which ordinary malic acid turns it to the left.

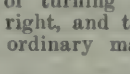
An optically inactive malic acid, which is really nothing but a mixture of equal quantities of the two modifications just described, may be prepared by a variety of chemical methods; it has been obtained from mono-bromo-succinic, fumaric, and malic acids, and from certain other substances. Though quite similar in its properties to the optically active modifications, it is found to be less soluble in water, to crystallize somewhat more readily, and to form crystals that are not deliquescent. The separation of its components may be effected by the crystallization of their cinchonine salts, which differ from each other to a marked degree in their physical properties.

Chemically, malic acid is a hydroxy-derivative of succinic acid, into which it is readily converted by the action of hydriodic acid at a high temperature. The chemical relationship of malic and succinic acids is shown by their constitutional formulas:



$$\begin{array}{l}\mathrm{CH(OH).COOH}\\ |\\ \mathrm{CH_2.COOH}\end{array}$$

Malic acid



$$\begin{array}{l}\mathrm{CH_2.COOH}\\ |\\ \mathrm{CH_2.COOH}\end{array}$$

Succinic acid

According to the thory of stereochemistry (q.v.), the existence of two modifications of malic acid is due to the fact that the molecule of the acid contains a carbon atom to which four different atomic groups are linked, viz., H, OH, COOH, and CH_2COOH. See Succinic Acid.

MAL'ICE (OF., Fr. *malice*, from Lat. *malitia*, badness, from *malus*, bad). In the most general sense, an evil or vindictive state of mind; in a more specific and technical sense, the mental attitude of one who does an unlawful act knowingly and willfully. It is in the former sense that the term is employed in defining the offenses of malicious mischief and of malicious prosecution. In neither of these cases is it enough to establish the fact that the defendant knowingly did the act of which he is accused or that he contemplated the consequences which must result from the act. In a prosecution for malicious mischief an evil disposition on the part of the accused must be shown, while in an action for malicious prosecution it must be made to appear that the defendant knew that there was no reasonable and probable cause for the prosecution instigated by him, from which the motive of actual malice will be inferred. The same distinction between intent and malice is drawn in prosecutions for trespass, the punitive or vindictive damages awarded in such cases being aggravated by proof of ill will or actual malice on the part of the defendant. On the other hand, malice, even though the motive of an act which injures another in his person or property, will not furnish grounds for an action unless the act inspired by it is itself unlawful. Except in a few American jurisdictions, it is uniformly held that the malicious exercise of a right (as where one erects a "spite fence" for the purpose of interfering with a neighbor's light or, with the motive of destroying a person's business, sets up a competing establishment) is not an actionable wrong. See Malicious Mischief; Malicious Prosecution; Tort; Damages.

In criminal law, on the other hand, malice usually signifies only the "criminal intent" of the wrongdoer, i.e., his purpose to commit the act which the law has forbidden. Malice, in this sense, is a necessary element of most crimes—of all, in fact, except those in which the mere possession of instruments of crime is made a criminal offense by statute. But this does not mean that the accused must have been animated by ill will towards the victim of his harmful act, but only that he willed or contemplated the act. It is no defense to an indictment for murder that the act was inspired by "love" or by a desire to save the victim from the pains of poverty or of a lingering disease. The malice, in such a case, is the purpose or intent to commit the forbidden act, i.e., the killing of another without legal excuse or justification. The employment of the term in this misleading sense has had the effect of seriously confusing the question of criminal responsibility in many cases. See Crime; Guilt; Intent; and articles dealing with particular crimes, as Murder; Burglary; Arson; Larceny; etc. For specific applications of the doctrine of malice, see Libel; Infant; Insanity.

MALICIOUS MISCHIEF. The specific criminal offense of willfully injuring or destroying the property of another from spite or ill will or with an intent to injure the owner. It does not include the unlawful appropriation of another's property, whether by force or fraud, however malicious the motive, nor acts of destruction, such as the wrongful cutting of timber by a tenant for life or years (civilly punishable as *waste*), or by a stranger (giving rise to an action of *trespass*), which are committed with the intent of appropriation and not from ill will. In short, to constitute the offense there must be physical injury to property and the object of the act must be to inflict damage on the owner or possessor. Except in the case of arson (where the motive with which the crime was committed is immaterial), the destruction of another's property, whether willful or not, was not an indictable offense at common law, the only penalty provided being the liability for damages in a civil suit (waste or trespass), though for a willful, and especially a malicious, trespass, punitive damages might be awarded. This defect of the common law was, however, corrected by statute at an early period, and malicious mischief, as above defined, is now a statutory offense both in England and the United States.

One of the leading English statutes is known as the Black Act, from a statement in the preamble that "several ill-designing and disorderly persons have of late associated themselves under the name of Blacks." This and a large number of other statutes were replaced in 1861 by a criminal consolidation Act (24 and 25 Vict., c. 97), which, with its amendments, extends the offense of malicious mischief to malicious injuries to most buildings, to fishponds, and various other classes of real property, and to almost any species of personal property. In the United States most of the State statutes are as sweeping and detailed in their provisions as those of England. In a few jurisdictions, however, the offense is confined to a limited class of injuries to personal property.

The intent with which the injury is inflicted must be malicious. As a rule, that term is used in this class of cases in its ordinary sense; i.e., actual malice must be shown. The Supreme Court of Massachusetts has declared that malice, in this connection, is "not sufficiently defined as the willful doing of an act prohibited by law for which the defendant has no lawful excuse, but the jury must be satisfied that the injury was done out of a spirit of cruelty, hostility, or revenge." Moreover, the malice must be entertained against the owner of the property, not against a third person or the property injured. These doctrines are modified in some States, especially where the statutes define the offense to consist in the willful infliction of unlawful injury. Occasionally a statute makes secrecy in doing the harm an essential element of the crime. In all jurisdictions it is a perfect defense that the injury was inflicted in the discharge of official duty or under an honest, though mistaken, claim of right. The offense is ordinarily classed as a misdemeanor, although in some jurisdictions it is declared a felony. See MALICE; and consult Harris, *Principles of the Criminal Law* (London, 1899); Bishop, *Commentaries on the Law of Statutory Crimes* (3d ed., Chicago, 1901); McClain, *Treatise on the Criminal Law, as now Administered in the United States* (ib., 1897).

MALICIOUS PROSECUTION. The civil wrong or tort of having prosecuted a person unsuccessfully and without probable cause. This was not a criminal offense at common law, but gave rise to a right of action for the injury suffered by the victim of the unjust prosecution. In a few of the American States the act has been made a criminal offense by statute. It is the right of every one to set the law in motion for the punishment of criminal offenses or for the enforcement of his individual claims. The courts have held that "public policy requires that parties may freely enter court to settle their grievances, and that they may do this without imminent exposure to a suit for damages in case of an adverse decision by judge or jury."

In order to recover, the plaintiff must establish by proof: (1) that the prosecution of which he complains was instituted by the defendant; (2) that it has terminated in plaintiff's favor; (3) that in instigating the prosecution the defendant acted maliciously and without reasonable and probable cause; and (4) that plaintiff was damaged by the prosecution.

The reason for requiring a termination of the original suit in the present plaintiff's favor before allowing him to sue for malicious prosecution is that it would not be consistent with the principles on which law is administered for another court, not being a court of appeal, to hold that a wrong decision was made in the original case. But the rule requiring a conclusive determination of the defendant's innocence of the offense for which he was prosecuted has no application to a proceeding which, from its nature, does not admit of such a trial—e.g., the search of one's house under a warrant for the discovery of stolen property or of incriminating evidence. If the search is fruitless and was instituted without probable cause, an action for malicious prosecution is maintainable. But the malice required to sustain such a suit is legal, not actual, malice; i.e., the malice is a legal presumption from the fact that no reasonable cause for the prosecution existed. If the defendant had good and sufficient grounds for instituting the prosecution of which the plaintiff complains, the fact that he was animated by ill will against the latter will not in most jurisdictions render him liable. It is generally held that the successful termination of the former action in the defendant's favor creates a presumption of law that the prosecution was unwarranted, but this presumption may be rebutted by showing that the prosecutor had reasonable cause for instituting it.

The truth of the circumstances alleged to show probable cause is a question of fact to be determined by the jury; but whether, admitting their truth, they amount to probable cause, is a question for the court. Frequently the person sued for malicious prosecution proves that the original proceeding was taken upon the advice of counsel. In order to shield himself behind such advice he must show not only that he consulted reputable and capable counsel, but that the advice was based upon a full and honest disclosure of all the material facts within his knowledge and belief.

Probable cause having been proved, the plaintiff must prove damage. Damage may be shown by proving that the proceeding was of a criminal character or, if a civil suit, that it was attended by an arrest of his person or seizure of his property or injury to his reputation (as in bankruptcy proceedings or an inquiry into his sanity), and in these cases he need give no evidence of special loss. "Such a prosecution necessarily and manifestly imports damages." But if the prosecution complained of was a civil suit, unattended by any of the incidents above referred to, the plaintiff must, in order to recover, show that it resulted in special loss or damage to him. Even though he is able to show this, he will be defeated in England and in many of the United States, on the doctrine that "in contemplation of law the defendant who is unreasonably sued in a civil action is sufficiently indemnified by a judgment in his favor which gives costs against his opponent." Consult: M. L. Newell, *Malicious Prosecution, False Imprisonment, and Abuse of Process* (Chicago, 1892); and the authorities referred to under Tort, such as Sir Frederick Pollock, *Law of Torts* (7th ed., London, 1904); F. M. Burdick, *Law of Torts* (3d ed., Albany, 1913).

MALIG′NANT CATARRH. An infectious disease of cattle which affects mainly the respiratory and alimentary tracts. It usually occurs in an enzoötic form and seems to persist in certain localities. The period of incubation is about three weeks. The disease ordinarily attacks young, vigorous animals and begins with a chill followed by high fever. The eyelids become swollen and the tear formation is abundant. The eyes are unusually sensitive to the light. There are thick bloody discharges from the nose and mouth. The mortality from the disease ranges from 50 per cent to 90 per cent, death occurring in from one to four weeks. There is no good specific treatment for the disease. The treatment should be symptomatic. Infected animals should be isolated and stables disinfected. Consult: United States Bureau of Animal Industry, *Special Report on Diseases of Cattle* (Washington, 1909); Hutyra and Marek, *Special Pathology and Therapeutics of Diseases of Domestic Animals*, vol. i (Chicago, 1912); E. W. Hoare, *A System of Veterinary Medicine*, vol. i (ib., 1913).

MALIGNANT DISEASE. A certain disease or type of disease which tends almost inevitably to a fatal issue. The tumors characterized as malignant are cancer and sarcoma. Some epidemic diseases assume, at certain times and in particular cases, a virulent, rapidly fatal form, and this is called the malignant or fulminant type of the disease. Among such diseases are scarlet, typhoid, and malarial fevers, endocarditis, purpura (qq.v.), and cerebrospinal meningitis. Other maladies, such as diphtheria and smallpox, have, through advances in medical knowledge, lost much of the severity that earned for them the title malignant. Smallpox has been almost entirely controlled by vaccination, and diphtheria rendered much less dangerous by the discovery of antitoxin; yet malignant cases of both these diseases occasionally occur. Among other diseases which, on account of their severity, have at one time or another been termed malignant are Asiatic cholera, bubonic plague, pernicious anæmia, acute yellow atrophy of the liver (malignant jaundice), and anthrax (malignant pustule).

MALIGNANT PUSTULE, or Anthrax; Wool-Sorters' Disease; Charbon; Milzbrand. An infectious disease produced by a rodlike bacillus, the *Bacillus anthracis*. It begins as an acute local inflammation. General infection may result. It is a very serious and generally fatal affection. Herbivorous animals are especially susceptible; less so the omnivora, and least of all the carnivora. It may occur in any part of the world. In man, the disease is always acquired from affected animals. Any part or tissue of an animal dead from anthrax is capable of communicating the disease. The dry bacillus can preserve its virulence for many years, and through any substance to which it may become attached the disease may be communicated; even the feet and proboscides of flies which have alighted upon the diseased animal (having in its tissues the bacillus) or upon the infected product may carry the disease. Ants and earthworms are believed to carry it from the buried animals to the grass above. Some minute scratch, abrasion, or insect bite may suffice for the inoculation; after this has taken place there come, in a few hours, itching and uneasiness. A pimple and then a blister follow, surrounded by a brawny induration of the skin; and œdema, with great swelling of the parts. The inflammation extends along the lymphatics and the neighboring lymph glands are swollen and tender. There is often high fever. Sometimes in the eyelid, and also in the head, hand, and arm, there may be very great œdema, so that gangrene may result. The constitutional symptoms are generally very grave.

The infection may be by way of the digestive tract, from eating the flesh or drinking the milk of diseased animals. There is then intense poisoning. A chill occurs followed by a fever, with vomiting, diarrhœa, and pains in the legs and back. There may then be shortness of breath, cyanosis, great anxiety and restlessness, and convulsions or spasms of the muscles. There may be hemorrhages from the mucous membranes. Malignant pustule may affect many individuals together, making a veritable epidemic. The site of inoculation must be destroyed by cautery or caustic. Injections of carbolic acid under the skin around the point of inoculation may prevent the spread of the infection. Internally, quinine and stimulants are appropriate. Sclavo's antianthrax serum has been used with success and should be given when obtainable. See Carbuncle; Anthrax.

MALIGNANTS. A sobriquet applied by the English Parliamentarians, in 1634 and subsequently, to those who adhered to the house of Stuart and refused to sign the Solemn League and Covenant, for which see Covenants, The.

MALIGNANT TUMOR. See Tumor.

MALIGNITE, mȧ-lĭg′nīt (named from the Maligne River, Ontario). An igneous rock, in aspect resembling a coarse-grained basalt (q.v.), but composed of about equal quantities of ægirine-augite and biotite, and of orthoclase feldspar and nephelene. Its relationships are closest with theralite and nephelene basalt.

MALÍNAO, mȧ-lē′nou. A town of Luzon, Philippines, in the Province of Albay. It is situated on the southwest shore of the Gulf of Lagonoy, 18 miles northwest of Albay, on the main highroad. It exports large quantities of hemp. Near by are found mineral springs and the extinct volcano Malínao. Pop., 1903, 12,437.

MALINES, mȧ′lēn′. A town of Belgium. See Mechlin.

MALING′ERING. The feigning of disease is common either for the purpose of exciting pity, to escape punishment for crime, to avoid military service, or for the sake of material gain, as in the case of professional beggars and those who bring action against transportation companies for alleged injuries. The malingerer may manufacture his symptoms entirely or merely exaggerate real symptoms. These affections are most easily simulated which present few marked characteristics to the ordinary observer, i.e., they must be subjective rather than objective. The expert is rarely deceived. Thus, pain, deafness, blindness, paralysis, and various degrees of insanity are simulated. The feigning of insanity by murderers in particular has become a common practice in some States. Transitory loss of mental balance due to emotional excitement or superinduced by excessive indulgence in alcohol or drugs is frequently alleged by wealthy or influential murderers in cases where the actual killing cannot be denied. This, when backed by a corroborative family history, the possession of certain physical stigmata, or eccentricities of behavior, real or assumed, and reënforced by an impressive array of expert evidence, has too often influenced juries to acquit the criminal or mitigate the severity of the verdict. Some cases of malingering have a basis in hysteria or neurasthenia; such patients are introspective and imaginative and often feign nervous maladies with surprising fidelity to nature. The expert can nearly always detect the imposture, but the sympathetic lay observer is readily deceived. In those countries where military service is compulsory, malingering, supplemented by deliberate maiming, as the destruction of one eye or the production of chronic discharge from the ears, is quite extensively practiced. To detect the malingerer various and ingenious tests have been devised. Pretended blindness and deafness can always be detected by appropriate tests. The X ray will show the presence or absence of a fracture. Simulated epilepsy may be detected by administering a pinch of snuff or a hypodermic injection of apomorphin. The electric current is employed to detect pretended unconsciousness and to differentiate many nervous diseases; and general anæsthesia will test the veracity of feigned muscular contractures, paralysis, wry neck, and similar conditions. Consult W. R. Smith, *Medical Jurisprudence* (London, 1913), and John Callie, *Malingering and Feigned Sickness* (New York, 1913). See Disease, *Feigning of Disease.*

MALINITZIN. See Marina.

MALL, mąl, măl, or mĕl, The. 1. An avenue on the north of St. James's Park, London, lined with rows of fine trees. 2. An avenue in Central Park, New York, extending from the Terrace and forming with the latter one of the most successful landscape effects of the park.

MALL, mąl, Franklin Paine (1862–1917). An American anatomist, born at Belle Plaine, Ia. He graduated M.D. from the University of Michigan in 1883, and studied also at the universities of Heidelberg and Leipzig, and at Johns Hopkins, where he was fellow (1886–88), instructor in pathology (1888–89), and professor of anatomy after 1893. He served also as adjunct professor of vertebrate anatomy at Clark University (1889–92) and as professor of anatomy at the University of Chicago (1892–93). In 1905–07 he was president of the Association of American Anatomists. He became coeditor of the *Handbuch der Entwicklungsgeschichte des Menschen*, the *American Journal of Anatomy*, the *Anatomical Record*, and the *Journal of Morphology;* and he is author of *Causes Underlying the Origin of Human Monsters* (1908).

MALLALIEU, măl'lȧ-lū', Willard Francis (1828–1911). A Methodist Episcopal bishop. He was born at Sutton, Mass.; graduated at Wesleyan University in 1857; and entering the ministry the next year was pastor of churches at Sutton, Boston, Chelsea, South Boston, and Worcester, Mass. He was presiding elder of the Boston district in 1882–84, a member of General Conferences (1872, 1876, 1880, and 1884), was elected Bishop in 1884, and was a member of the Ecumenical Methodist Conference of 1891. His official episcopal residences were New Orleans (1884–92), Buffalo (1892–96), and Boston (1896–1904). He was retired from active work by the General Conference of 1904. He was the author of *The Why, When, and How of Revivals* (1901); *The Fullness of the Blessing of the Gospel of Christ* (1903; Spanish trans., 1909); *Words of Cheer and Comfort* (1907).

MAL'LARD (OF. *malard, malart*, probably from *male, masle*, male, from Lat. *masculus*, male, from *mas*, man). A handsome wild duck (*Anas boschas*, or *platyrhynchos*), found in most parts of the Northern Hemisphere outside of the tropics. It is about 2 feet long and weighs two or three pounds. The female has dusky and tawny-brown feathers, but the plumage of the male is glossy green on the head, purplish chestnut on the breast, black on the back, and a finely crossbarred silver gray on the belly. He also has a tuft of curly feathers above the tail. The mallard is the well-known original stock of the common domestic duck, and in its breeding and other habits it closely resembles barnyard birds. It is rare in New England, and breeds mostly north of the United States, making its nest on the ground in a marsh and lining it copiously with feathers. See Duck; and Colored Plate with Water Birds.

MALLARD, mȧ'lär', François Ernest (1833–94). A French engineer and mineralogist, born at Châteauneuf-sur-Cher. He entered the Ecole Polytechnique in 1851 and two years afterward passed to the School of Mines, where he was appointed professor of mineralogy (1872). In 1886 he was made an inspector general with supervision over the departments of the Northeast. He became a member of the Academy of Sciences in 1890. Besides a great number of memoirs on scientific subjects he wrote an important *Traité de cristallographie géométrique et physique* (1879–84), and produced a *Carte géologique du département de la Haute-Vienne.*

MALLARMÉ, mȧ'lär'mȧ', Stéphane (1842–98). A symbolistic French poet, born in Paris. He was professor of English in the Lycée Fontanes. More than Paul Verlaine (q.v.), Mallarmé led the Symbolistic school of poetry. In 1876 he aroused attention with *L'Après-midi d'un faune*, illustrated by the painter Manet. In 1878 appeared his *Petite mythologie à l'usage des classes et du monde.* In 1880 he published *Les dieux antiques: nouvelle mythologie* and Beckford's *Vathek*, with a preface; in 1886, a translation of Poe's *Raven;* in 1887, *Poésies.* His rendering of Poe's *Poems* appeared in 1888; *Vers et prose* in 1893. Some readers find beauty in Mallarmé, but to most readers his prose and his verse seem willfully obscure. Almost from the outset his poetic efforts were the talk of literary Paris. Some critics regarded him as an unusual phenomenon and tried to explain him. In 1895 Lanson expressed the widespread opinion that Mallarmé was a poet of very slight value. Gaston Paris benevolently remarked that Mallarmé was worthy of study. By the small set of Décadents and by their admirers he was heralded as a writer of the highest order, but he had few readers, and his notoriety soon began to wane. About Mallarmé cluster a score or so of Symbolists. The best known are Henri de Régnier, Jean Moréas, Emile Verhaeren, Fleming, Gustave Kahn, and finally Maeterlinck (q.v.). Consult Edmund Gosse, *Questions at Issue* (New York, 1893), and Francis Grierson, *Parisian Portraits* (London, 1913).

MALLEABIL'ITY (from *malleable,* Fr. *malléable,* from ML. *malleare,* to beat with a hammer, from Lat. *malleus,* hammer). The property which certain metals possess of being reducible to thin leaves, either by hammering or by lamination between rollers. The order in which the malleable metals exhibit this property is as follows: gold, silver, copper, platinum, palladium, iron, aluminium, tin, zinc, lead, cadmium, nickel, cobalt. Gold far surpasses all the other metals in malleability, being capable of reduction into films not exceeding the 200,000th of an inch in thickness; silver and copper also may be reduced to leaves of great tenuity. Although gold and silver also present the property of *ductility* (q.v.) in the highest degree, there is no constant relation between the two properties; e.g., iron, although it may be reduced to extremely thin wire, is not nearly so malleable as gold, silver, or copper.

MALLECO, mȧ-lyā'kō. A province of Chile, bounded by Argentina on the east, the provinces of Cautin on the south, Bio-Bio on the north, and Arauco on the west (Map: Chile, E 5). Its area is 2973 square miles. It is mountainous in the eastern and western parts and is well wooded. Timber and wheat are the chief products. The province is traversed by two railway lines. Pop., 1885, 58,983; 1895, 98,032; 1907, 109,775. A considerable portion of the population consists of Araucanian Indians. The capital is Angol (q.v.).

MALLEE (măl'ē) **BIRD.** See MOUND BIRD.

MAL'LERY, GARRICK (1831–94). An American ethnologist and soldier, born at Wilkes-Barre, Pa. He graduated at Yale in 1850 and practiced law in Philadelphia until the outbreak of the Civil War, when he enlisted in the Federal army, in which he rose to the brevet rank of colonel. He was connected with the Signal Service Bureau in 1870–76, made investigations among Dakota and other western tribes of Indians in 1876–79, and from 1879 until his death he was ethnologist of the Bureau of Ethnology. Among his publications are: *The Former and Present Number of our Indians* (1877); *A Calendar of the Dakota Nation* (1877); *Introduction to the Study of the Sign Language among the North American Indians* (1880); *Pictographs of the North American Indians* (1886); *Israelite and Indian: A Parallel in Planes of Culture* (1889); *Picture Writing of the American Indians* (1893).

MAL'LESON, GEORGE BRUCE (1825–98). An Anglo-Indian official and historian, born in London. He was educated at Winchester and served 35 years in India, 10 of which were in the army and the rest in government positions. He was sanitary commissioner to the government of India (1866–68), comptroller general of military finances (1869), and the guardian of the Maharajah of Mysore (1869–77). He obtained the rank of colonel in 1873. He died March 1, 1898. Malleson wrote many books, dealing mostly with India, of which the best is *The French in India* (1868) and the longest is *The History of the Indian Mutiny* (1878–80), a continuation of Sir John Kaye's *History of the Sepoy War.* Among his other works are: *Recreations of an Indian Official* (1872); *Final French Struggles in India* (1878); *History of Afghanistan* (1879); *The Founders of the Indian Empire* (1882); biographies of Akbar (1890), Dupleix (1890), Clive (1882), Hastings (1894), Wellesley (1889); *The Refounding of the German Empire* (1893); *Lakes and Rivers of Austria, Bavaria, and Hungary* (1897).

MAL'LET (originally **MALLOCH**), DAVID (c.1705–65). A Scottish writer and poet, born near Crieff (Perthshire). He studied at Edinburgh University and afterward lived principally in London, where for some time he was one of the secretaries of the Prince of Wales. He changed his name to Mallet when he went to live in England. He was at first a friend and admirer of Pope, but to please his patron, Bolingbroke, he attacked Pope's memory in a preface he wrote for Bolingbroke's *Patriot King* (1749). Mallet again sold his pen during the popular indignation against Admiral Byng in 1757. His works include: *William and Margaret* (1723); *The Excursion* (1728); *Verbal Criticism* (1733); *Amyntor and Theodora, or the Hermit* (1747), poems; and some mediocre plays. He also published two volumes of *Poems on Several Occasions* (1743, 1762). An edition of his works appeared in 1759.

MALLET, JOHN WILLIAM (1832–1912). An American chemist, son of Robert Mallet. He was born in Dublin, was educated there at Trinity College and at Göttingen, and in 1853 came to the United States to become chemist of the Geological Survey of Alabama. He was professor of chemistry in the University of Alabama (1855–60) and in the State Medical College until the Civil War. Mallet served on General Rodes's staff and as manager and director of the ordnance laboratories of the Confederate States. After the war he was professor of chemistry at the University of Louisiana until 1868; then he went to the University of Virginia, where he became emeritus professor of chemistry in 1908. In 1882 he served as president of the American Chemical Society. With his father he prepared for the British Association a catalogue of earthquakes (1858). Alone he published: *Cotton* (1862); *Chemistry Applied to the Arts* (1868); *Syllabus of a Course of Lectures on General Chemistry* (1890; rev. ed., 1901); and contributions to chemical journals.

MALLET, ROBERT (1810–81). An Irish civil engineer, born in Dublin, where he graduated B.A. from Trinity College in 1830. He engaged in various industrial-engineering, bridge-building, and railroad operations; built the Fastnet Rock Lighthouse in 1848–49; invented the Mallet buckled plate in 1852; and became a consulting engineer in London in 1861. He was elected a fellow of the Royal Society in 1854. His scientific work, especially in regard to his investigations of the causes of volcanic action, won him the Wollaston medal in 1877. He published: *The Earthquake Catalogue of the British Association* (1858), with his son J. W. Mallet (q.v.); *Great Neapolitan Earthquake of 1857* (2 vols., 1862); *The First Principles of Observational Seismology* (1862). He edited the *Practical Mechanic's Journal* in 1865–69.

MALLINGER, mäl'ĭng-ĕr, MATHILDE (1847–1920). A celebrated Hungarian dramatic soprano, born at Agram. She received her first instruction from her father, then studied for two years (1863–65) at the Prague conservatory and for one year with Richard Lewy in Vienna. In 1866 she made her début in Munich as Norma, where her extraordinary success immediately led to a three years' engagement. Her splendid voice and histrionic ability attracted the attention of Wagner, who chose her as the original interpreter of Eva in *Die Meistersinger* (1868). In 1869 she was married to Baron Schimmelpfennig and removed to Berlin, where she was one of the brightest stars of the Royal Opera until 1882. She then retired from the stage at the height of her fame and powers. From 1890 to 1905 she was professor of singing at the Prague conservatory, returning to Berlin as a member of the Eichberg Conservatory.

MALLOCH, mål′ŏk, David. See Mallet, David.

MAL′LOCK, William Hurrell (1849–). An English writer on social and religious questions. He was born in Devonshire and was educated at Balliol College, Oxford, where he won the Newdigate prize of 1872 with a poem on *The Isthmus of Suez.* He was intended for a diplomatic career, but devoted himself entirely to literature, spending a considerable part of his life in southern and eastern Europe. His writings, even in fiction, are generally occupied to a large extent with current problems of thought and life. In philosophy he aimed to show that modern science can of itself offer no firm basis for ethical or religious theory. Under this head comes *Atheism and the Value of Life* (1884); but his most powerful book in this class, *Is Life Worth Living?* (1879), is a cogent criticism of the Positivist position as set forth by its own advocates. In this book, and still more in *Doctrine and Doctrinal Disruption* (1900), he argues for a sure dogmatic foundation for religious belief, and his logic favors the Roman Catholic church, with which, however, he did not actually connect himself. In *The New Republic* (1877), under thin disguises, several of the most famous Englishmen of the time appear and discuss many of the great problems of life. Two novels, *A Human Document* (1892) and *The Heart of Life* (1895), are largely occupied with modern aspects of the relations of the sexes, as is to a certain extent *A Romance of the Nineteenth Century* (1881). *The Old Order Changes* is a counterblast to Socialism under the form of fiction, and this is the standpoint of various important economic works—*Social Equality* (1882); *Property and Progress,* an answer to Henry George (1884); *Classes and Masses* (1896); and especially *Aristocracy and Evolution* (1898). Among his other publications are: *Religion as a Credible Doctrine* (1902); *The Reconstruction of Belief* (1905); *The Nation as a Business Firm* (1910). His economic and social writings did not grow in authority with the years, and he suffered considerably from unceremonious treatment in Bernard Shaw's *Socialism and Superior Brains* (1910).

MALLOPH′AGA (Neo-Lat. nom. pl., from Gk. *μαλλός, mallos,* wool + *φαγεῖν, phagein,* to eat). An order of wingless parasitic insects, commonly called bird lice or biting lice. The latter name is preferable, since they occur upon mammals as well as upon birds and are distinguished from the true lice of the hemipterous family Pediculidæ (see Louse) by possessing biting mouth parts. They do not suck blood as do the true lice, but feed upon the feathers or hair of the birds or mammals upon which they are found, just as do the bird mites. (See Mite.) The metamorphosis is incomplete; the body is greatly flattened and generally hard; the head is large and flat; the antennæ are short and from three to five jointed; the eyes are simple; and the jaws are usually toothed and pointed. The front legs are short and are used only in carrying food to the mouth, projecting forward beneath the head when the insect is at rest. The other legs are strong, and the whole body is usually rather hairy. The eggs are elongate-oval and are fastened singly to the feathers or hairs of the host animal. The young issue by breaking off a circular lid at the free end of the egg. More than a half dozen species of bird lice, belonging to three distinct genera, have been found upon the common domestic chicken. Nearly all are cosmopolitan species and have been carried to all parts of the world. *Goniocotes hologaster* is the commonest of these although *Goniocotes abdominalis* is also very abundant. *Lipeurus opaculus* is a common form found upon pigeons, and *Lipeurus polytrapezius* occurs abundantly upon turkeys. The domestic cat is often infested by *Trichodectes subrostratus,* and the dog by *Trichodectes latus.* The habit which fowls have of scratching in the dust and throwing it over their backs is an indication that they are infested. The best remedy consists in the free use of pyrethrum or Persian insect powder and of kerosene.

Consult: Herbert Osborn, *Insects Affecting Domestic Animals* (Washington, 1896); V. L. Kellogg, "A List of the Biting Lice taken from Birds and Mammals of North America," in *Proceedings of the United States National Museum* (ib., 1899); id., "New Mallophaga," in *Hopkins Seaside Laboratory Contributions,* Nos. iv, vii, and xix (Palo Alto, 1896–99); Kellogg and Paine, "Mallophaga from Birds of India," in *Records of the Indian Museum,* vol. x (Calcutta, 1914).

MALLORCA, mȧ-lyôr′kȧ. One of the Balearic Islands. See Majorca.

MALLORE, Sir Thomas. See Malory, Sir Thomas.

MAL′LORY, Stephen Russell (1813–73). A cabinet officer in the Confederacy. He was born in Trinidad, West Indies, and in 1832 was appointed by President Jackson inspector of customs at Key West. About 1839 he was admitted to the bar, subsequently served in the Florida War against the Seminole Indians, and from 1851 to 1861 represented Florida in the United States Senate. In the latter year Florida seceded from the Union, and Mallory was appointed Secretary of the Confederate navy, then without a ship. His only preparation for this post, which he held throughout the Civil War, was his experience as chairman of the Senate Committee on Naval Affairs; nevertheless he showed great executive ability in promoting the construction and arming of the Confederate navy. After the war he was imprisoned, but in 1866 was released on parole, went to Pensacola, Fla., and practiced law there until his death.

MAL′LOW (AS. *malwe, mealwe,* from Lat. *malva,* from Gk. *μαλάχη, malachē, μολόχη, molochē,* mallow, probably from *μαλάσσειν, malassein,* to soften, from *μαλακός, malakos,* soft, from Heb. *mallūah,* marshmallow, from *mālah,* to flow, so called probably from its emollient qualities or, less plausibly, from the softness of the leaves), *Malva.* A genus of plants of the family Malvaceæ (q.v.). The species, which number about 30, are herbs, or more rarely shrubs. The common mallow (*Malva sylvestris*), which is plentiful in most of Europe and in America on waysides and heaps of rubbish, is a perennial, with rather large bluish-red flowers on erect stalks. The dwarf mallow (*Malva rotundifolia*), now a common weed in America, has smaller whitish or reddish-white flowers. These two plants and other species are mucilaginous and somewhat bitter. The musk mallow (*Malva moschata*), not unfrequent in America, has a faint musklike smell. The fibre of *Malva crispa* is used in Syria for textile purposes, and the fibres of many species are probably fit for similar use, and for the manufacture of paper. The young leaves of some are said to be occasionally used as boiled vegetables. *Malva alcea* resembles the musk mallow in general appearance and is often cultivated. It is a perennial with deep rose-colored flowers often veined with dark red. A number of cultivated plants are often called mallows, but most of them belong to other genera of the mallow family.

MAL′MA. A vernacular name in Kamchatka, adopted as the specific designation, and sometimes used as the common name, of the bull or Dolly Varden trout (q.v.).

MALMAG. See Tarsier.

MALMAISON, mȧl′mȧ′zôɴ′ (Lat. *mala mansio*, evil dwelling), La. A château near Versailles, France, some 7 miles west of Paris, known as the home of Josephine Beauharnais before her marriage to Napoleon and after her divorce in 1809. The history of the place may be traced to the thirteenth century, when it obtained its name from its reputation as a resort for outlaws.

MALMESBURY, mämz′bẽr-ĭ. A market town in Wiltshire, England, 94 miles west of London (Map: England, D 5). It is an interesting town, picturesquely built on an eminence almost surrounded by the lower Avon. A castle existed here in the seventh century, when a monastery was also founded. The celebrated chronicler William of Malmesbury was a monk in the abbey, which afterward became a cloth factory. The remains of the abbey church, partly early Norman and partly decorated English, may still be seen. It was the burial place of Athelstan and the birthplace of the philosopher Hobbes. The church of Garsdon, 2 miles distant, contains many memorials to the Washington family and the manor house of Sir Lawrence Washington (died 1643), now a farm. Pop., 1901, 2900; 1911, 2656. Consult *Registrum Malmesburiense*, edited by Brewer and Martin (London, 1879–81), and Perkins, *Malmesbury Abbey* (ib., 1901).

MALMESBURY, James Harris, first Earl of (1746–1820). An English diplomat, born at Salisbury, April 21, 1746, and educated at Winchester, Oxford, and Leyden. At the age of 21, through the influence of Lord Shelburne, he was appointed Secretary of the Embassy at Madrid. His skillful diplomacy there as chargé d'affaires at the time of the dispute between England and Spain in regard to the Falkland Islands led to his appointment in 1771 as Minister Resident at Berlin, where he remained four years. In 1777 he was made Ambassador to Russia. The state of his health compelled him to leave St. Petersburg in 1783, but next year he accepted from the Pitt ministry the post of Minister to The Hague. In 1788 he brought about an alliance of England with Holland and Prussia, which service gained for him the title of Baron Malmesbury. Returning to England, he entered Parliament, of which, in spite of his long absences, he had been a member since 1770. He was a Whig till 1793, when he became a supporter of the administration, and Pitt sent him to negotiate a treaty between England, Prussia, and Holland—a mission which he successfully discharged. In 1794 he arranged the marriage between the Prince of Wales and Caroline, daughter of the Duke of Brunswick. His fruitless negotiations for peace with the French Republic in 1796 at Paris and next year at Lille were his last missions, as he now deemed himself incapacitated by growing deafness from taking further part in public affairs, except as an adviser of the men of both parties, by whom, for several years, he was freely consulted. In 1800 he was made Earl of Malmesbury and Viscount Fitzharris. He died Nov. 21, 1820. Consult his *Diaries and Correspondence* (4 vols., London, 1845); *Lord Malmesbury and his Friends: Letters from 1745 to 1820* (ib., 1870), both edited by J. H. Harris, his grandson; *Lord Malmesbury's Embassy: Official Documents in the Negotiations at Lisle* (Edinburgh, 1797); W. E. Auckland, *Journal and Correspondence* (London, 1861–62); P. H. S. Stanhope, *Life of Pitt* (4 vols., ib., 1861).

MALMESBURY, James Howard Harris, third Earl of (1807–89). An English statesman. He was educated at Eton and at Oriel College, Oxford; was returned to Parliament as a Conservative in 1841, but succeeded his father in the peerage the same year. He became Secretary for Foreign Affairs in Lord Derby's first administration (1852). Lord Malmesbury occupied the same position in the second cabinet of Lord Derby (1858–59), when he endeavored to prevent the war between France and Sardinia and Austria. In 1866 he became Lord Keeper of the Privy Seal, remaining in office till 1868. From 1874 to 1876 he was again Privy Seal. He edited the *Diaries and Correspondence* of his grandfather (London, 1845) and *The First Lord Malmesbury and his Friends* (London, 1870). Consult *Memoirs of an Ex-Minister: An Autobiography* (London, 1884; 4th ed., 1885), and L. C. Sanders, in *Dictionary of National Biography*, vol. xxv (ib., 1891).

MALMESBURY, William of. An English chronicler. See William of Malmesbury.

MALMIGNATTE, măl′mė-nyăt′ (corruption of the Corsican name *marmignatto*). A spider of the genus *Latrodectus*, common in southern Europe, whose bite is much dreaded. See Spider; and cf. Tarantula.

MALMÖ, măl′mẽ. A seaport of Sweden, the capital of the Län of Malmöhus, and the third largest city in the country. It is situated on the Sound, opposite Copenhagen, with which it is connected by ferry (Map: Sweden, E 9). The old part of the city is entirely surrounded by canals, inside of which the old fortifications have been razed, and their sites converted into beautiful parks and boulevards. Among the most prominent buildings are the fine city hall, built in 1546 in the Dutch Renaissance style, the old Gothic church of St. Peter, begun in 1319, and the Governor's residence. The Malmöhus, an old fortified castle of the fifteenth century, is now used as a prison; in it Bothwell, husband of Mary, Queen of Scots, was imprisoned from 1567 to 1573. Malmö is an important industrial centre and has some of the largest ironworks and foundries in the country, besides manufactures of railroad and tram cars, textiles, shoes and gloves, tobacco, brandy, and chocolate. It is the terminus of eight railroad lines, has the largest artificial harbor in Scandinavia, and regular steamship connection with many foreign cities besides Swedish towns. There is a lively export trade in the agricultural products of the exceedingly fertile Province of Skåne, of which it is the capital, and the chief imports are coal and raw cotton. Its population has more than trebled since 1860, and in 1901 was 60,857 and in 1912, 92,338. Malmö is first mentioned in the early part of the twelfth century, when its name was Malmöghe, or Malmhauge, which means "sand bank." It was then a fishing village, but by the beginning of the sixteenth century it was, next to Copenhagen, the largest and most important city of the Danish possessions. During the wars of the following period it declined until the opening of its harbor in 1775, when its prosperity began to return. In 1658 it came into the possession of Sweden, together with the district of the Skåne. The present prosperity of the town dates from the construction of the harbor at the end of the eighteenth century and the opening of the railroad to Stockholm in 1856.

MALMSTRÖM, mälm′strẽm, BERNHARD ELIS (1816–65). A Swedish poet and author, born in the Province of Nerike. He studied at the University of Upsala and afterward became dean and professor of æsthetics and literature there (1856). His poetical works, though few in number, have placed him among the first of Swedish poets. They include: *Fiskarflickan på Tynnelsö* (1839) (The Fisherman's Daughter); *Angelika* (1840), an elegy, which won him the prize of the Swedish Academy; *Julianus* (1841); *Dikter* (1845–47; 9th ed., 1897). Among his prose writings are *Litteraturhistoriska Studier* (1860–61). His complete works were published posthumously, *Samlade Skrifter* (8 vols., 1866–69).

MALMSTRÖM, JOHAN AUGUST (1829–1901). A Swedish historical and genre painter and illustrator. He was born at Vestra Ny, East Gothland, and studied at the Stockholm Academy, Düsseldorf, Paris, where he became a pupil of Couture, and in Rome. After his return (1864) he was made professor at the Stockholm Academy (1867), and from 1887 to 1893 he was director. His subjects are chosen chiefly from Norse history and sagas. They are painted with romantic delicacy and a certain technical skill, especially as regards the treatment of light. Such are "King Heimar and Aslög"; "Sport of Elves"; "The Bråvalla Battle." In later years he also painted fresh and spirited genre pictures of child life. He illustrated *Fridthjof's Saga* (1868), *Fenrik Stål*, and other northern legends, and fairy tales of Asbjörnsen and Topelius.

MALO, mȧ′lō′, CHARLES ALBERT (1851–1912). A French military writer, born at Pin-le-Haras in Orne. He took part in the Franco-German War, receiving in 1870 the médaille militaire for his bravery at Metz. But he was made prisoner and spent the rest of the war in a German fortress. After his return to France he was on the staff of the War Department. In 1879 he became editor of the *Journal des Débats* and in 1885, in conjunction with Berger-Levrault, founded the *Revue de Cavalerie*, remaining chief editor until 1911. His most important works are the summaries or technical descriptions of campaigns that he contributed to Marquhardt's *Bibliothèque internationale d'histoire militaire*, among them *Campagne de 1805 en Allemagne et en Italie* (1886); *La guerre de 1866 en Allemagne et en Italie* (1886); *Campagnes de Gustave-Adolphe* (1887); *La situation militaire de la Belgique dans le cas d'une guerre franco-allemande* (1887); *Campagnes de Turenne* (1888); *L'Armée suisse en 1889* (1890); *M. de Moltke* (1891). Of his other works may be mentioned *Champs de bataille de l'armée française* (1900), treating of battlefields in Belgium, Germany, and Italy; and *Champs de bataille de France* (1900), referring to his own country; *Le Général Gallifet* (1910).

MALOLOS, mȧ-lō′lōs. The capital of the Province of Bulacán, Luzon, Philippines (Map: Philippine Islands, C 3). It is situated on an arm of the Pampanga Delta, 5 miles northwest of Bulacán Bay. It has a telegraph station and lies within a short distance of a station on the Manila Railroad, being a considerable trade centre. It was the first capital of the so-called Philippine Republic, proclaimed by the natives after the Spanish-American War, but was soon abandoned by the insurgent government. The chief product of the vicinity is rice. Pop., 1903, 12,575.

MALON, mȧ′lôɴ′, BENOÎT (1841–93). A French Socialist, born near Saint-Etienne in the Department of Loire. Because of his agitation on behalf of the International he had to leave France for some years. He returned in 1880 and later edited the *Revue Socialiste* until his death at Asnières, Sept. 13, 1893. Malon did not think the social question to be as simple as did the German Socialists, and believed that religion, ethics, and æsthetics would bear their part in solving the problems. He was a man of fine character and great influence. He wrote: *L'International, son histoire et ses principes* (1872); *Histoire du socialisme et des prolétaires* (1881–84); *Le socialisme réformiste* (1885); *Le socialisme intégral* (1890–91).

MALONE, mȧ-lōn′. A village and the county seat of Franklin Co., N. Y., 61 miles by rail east by north of Ogdensburg, on the Salmon River and on the Rutland and the New York Central and Hudson River railroads (Map: New York, F 1). It is the seat of Northern New York Institution for Deaf Mutes and has Franklin Academy, the Alice Hyde Memorial Hospital, and the school district library. The village controls extensive agricultural interests and is an important industrial centre, having railroad shops, tanneries, woolen, pulp and paper, and flour mills, shirt factory, foundries and machine shops, sash, door, and blind factories, etc. There are municipal water works. The government is administered by a mayor, annually elected, and a village council, chosen on a general ticket. Malone was settled about 1803. Pop., 1900, 5935; 1910, 6467.

MALONE, EDMUND (1741–1812). A British scholar and editor of Shakespeare, born in Dublin, Oct. 4, 1741, educated at Trinity College, Dublin, and called to the Irish bar (1767). In 1777 he settled in London and began a systematic study of Shakespeare. He soon gained admission to the best literary circles of the day. In 1778 he published his *Attempt to Ascertain the Order in which the Plays of Shakespeare were Written.* This work, the first of the kind, was so well done that it has withstood, in the main, the most recent application of verse tests. In 1780 Malone published two important volumes as supplementary to Johnson's edition of Shakespeare as revised by George Steevens. From 1789 through 1790 he assisted Boswell in revising his *Life of Johnson.* In 1790 appeared his edition of the dramatist in 10 volumes. At his death, April 25, 1812, he left material for a new edition, which was prepared by James Boswell, the younger. It appeared in 1821 in 21 volumes and is known as the Third Variorum. Though not very well arranged in parts, it still remains the best of all complete critical editions. Malone has been called dull; he was certainly laborious and painstaking. He also edited *The Critical and Miscellaneous Prose Works of Dryden,* containing a valuable introductory essay (4 vols., 1800); took part in the Chatterton controversy with *Cursory Observations on the Poems Attributed to Thomas Rowley* (1782); and exposed the Ireland forgeries (1796). Consult: *Life,* by James Prior (London, 1864); Leslie and Taylor, *Life of Sir Joshua Reynolds* (ib., 1865); and Boswell's *Life of Johnson,* edited by G. B. Hill (Oxford, 1887), passim.

MALONE, John (1854–1906). An American actor and writer, born in Westfield, Mass., but brought up on the Pacific coast. In 1880 he went upon the stage in San Francisco. He played with Edwin Booth (1886–87), Mrs. Langtry (1888), Tommaso Salvini (1889–90), Modjeska (1897), and Richard Mansfield. Later he devoted himself to the writing of criticism.

MALOO (mä′lo͞o) **CLIMBER.** An East Indian climbing plant. See Bauhinia.

MALON′IC ACID, $CH_2(COOH)_2$. A chemical compound of carbon, hydrogen, and oxygen first obtained in 1858 by Dessaignes. It is now usually prepared by boiling cyanoacetic acid, $CH_2(CN)\cdot COOH$ (see Malonic Ester), with dilute acids or alkalies. Malonic acid is a white crystalline substance that melts at 134° C. (about 273° F.). It is very soluble in water, alcohol, and ether. Owing to the fact that two carboxyl (COOH) groups are linked in its molecule to one carbon atom, malonic acid loses a molecule of carbon dioxide (CO_2) when heated above its melting point, especially when heated at 180° C. (356° F.), and is thus transformed into acetic acid, CH_3COOH. See Malonic Ester.

MALONIC ESTER, or Diethyl Malonate, $CH_2(COOC_2H_5)_2$. An important compound of carbon, hydrogen, and oxygen, used in the synthesis of a number of organic substances. It is usually obtained by heating cyanoacetic acid with sulphuric acid in alcoholic solution. When pure it forms a colorless liquid that boils at 198° C. (about 388° F.); at low temperatures it congeals to a white crystalline mass that melts at about $-50°$ C. ($-58°$ F.). Its importance in synthetic chemistry is due to the fact that one of the two hydrogen atoms of its CH_2 group can be readily replaced by sodium, yielding the compound $CHNa(COOC_2H_5)_2$, which reacts with halogen derivatives of the hydrocarbons, the product being malonic ester with one of the hydrogen atoms of the CH_2 group replaced by a hydrocarbon radicle; when this substituted malonic ester is hydrolyzed (transformed into its acid) and the resulting substituted malonic acid is heated to about 180° C. (356° F.), carbon dioxide is evolved, and there remains behind a substituted acetic acid.

MAL′ORY, or **MALLORE,** Sir Thomas (flourished 1470). Author of the *Morte d'Arthur.* Nothing certain about him is known beyond the meagre statements in the preface and the closing passage of his famous book. He was a knight, and his translation was completed in the ninth year of the reign of King Edward IV, i.e., in 1469 or 1470. According to Bale (*Scriptores,* 1548), he was a Welshman; and with Bale agree several recent Celtic scholars, asserting at least that his name is derived from the Welsh *Maelor.* With more probability G. L. Kittredge has identified him with a Warwickshire Thomas Malory, Knight, who died March 14, 1470. Malory placed the manuscript of the *Morte d'Arthur* in the hands of William Caxton, who divided it into books and chapters and printed it in 1485. The contents are briefly summarized in the colophon: "Thus endeth thys noble and joyous book entytled le morte Darthur/ Notwythstondyng it treateth of the byrth/ lyf/ and actes of the sayd kyng Arthur/ of his noble knyghtes of the rounde table/ theyr meruayllous enquestes and aduentures/ th' achyeuyng of the sangreal/ & in thende the dolorous deth & departyng out of thys world of them al." The book was intended as a compendium of the various romances that had attached themselves to the legend of King Arthur. Here are the great stories of Lancelot and Guinevere, of Tristram and Iseult, and of most of the knights and ladies as known to the reader of Tennyson's *Idylls of the King.* Caxton expressly states that Malory reduced his book into English out of certain French books. So far as is known, these sources were the prose Merlin, the prose Lancelot, and the prose Tristan (thirteenth century), which in turn were expansions of Geoffrey of Monmouth, *History of the British Kings* (Latin prose), and the verse tales of Chrestien de Troyes and other French romancers (second half of twelfth century). Malory also made use of a fine English poem, known as the *Morte Arthur* (fourteenth century). Malory's compendium is necessarily loose in structure; but the career of King Arthur gives it a certain unity. It enjoys the distinction of being the first notable English prose romance.

The *Morte d'Arthur* was well received from the first. Caxton's edition in black letter was followed by six similar editions down to 1634. The work was not again reprinted till 1816, when two editions appeared. It is now accessible in the editions of Thomas Wright (London, 1856; new ed., 1897), Edward Strachey (modernized in spelling, Globe ed., ib., 1868; often reprinted), Ernest Rhys (ib., 1909), and Oskar Sommer (ib., 1889–91). The last, a reprint of the first edition, contains an exhaustive study by Sommer on the sources, and an essay by Andrew Lang on the style. The most popular modern editions are the Temple Classics, edited by Israel Gollancz (London, 1897 et seq.), and Everyman's Library, edited by Ernest Rhys (ib., 1908). Consult also: Jusserand, *Le roman au temps de Shakespeare* (Paris, 1888); C. S. Baldwin, *Inflections and Syntax* (Boston, 1894); G. L. Kittredge, "Who was Sir Thomas Malory?" in *Harvard Studies and Notes,* vol. v (Cambridge, Mass., 1896); *Selections,* edited by Mead (Boston, 1897); *Boy's King Arthur,* edited by Sidney Lanier (New York, 1908). See Arthur; Grail, The Holy; Lancelot; Merlin; Tristram; Geoffrey of Monmouth.

MALOT, mȧ′lō′, Hector (1830–1907). A popular French novelist, born near Rouen. Though educated for the law he turned to letters, served an apprenticeship on Didot's *Dictionnaire* *biographique* and the popular *Journal pour Tous*, did some dramatic collaboration of no present significance, and in 1859 produced his first novel, *Victimes d'amour*, a book of more promise than was afterward realized. In some 65 volumes he dealt with the society of the Second Empire, showing a tendency to sensationalism, a power of graceful description, and a very winning sympathy for child life that made his *Sans famille* (*No Relations*, 1878; translated and republished in America) a cosmopolitan success. Other noteworthy works are: *Un beau-frère* (1869); *Romain Kalbris* (1869); *Baccara* (1886); *Conscience* (1888); *Justice* (1889); *Complices* (1893); *En famille* (1893); *Amours de jeune, amours de vieux* (1896). In 1897 he wrote *Le roman de mes romans*. This was a literary biography and his last work.

MALPIGHI, mȧl-pē′gē̇, MARCELLO (1628–94). A celebrated Italian anatomist, born at Crevalcore, near Bologna. He studied medicine at Bologna under Massari and Mariano, took his doctor's degree in 1653, and was appointed professor at Bologna by the Senate three years later. Shortly after this he went to Pisa, where, in association with Borelli, he made numerous dissections of animals and ascertained that the muscle fibres of the heart are of a spiral form. The climate of Pisa proving unfavorable, Malpighi removed to Bologna in 1659, where he remained three years and became very popular. In 1662 he succeeded Peter Castelli at Messina. In 1691 the new Pope, Innocent XII, called him to Rome as his physician, and three years later he died of apoplexy, at the age of 66.

Malpighi lived at a time when nature began to be studied rather than books. He was an original and profound observer, a man of great industry, acute intelligence, and natural aptitude for research. His investigations covered a wide range of subjects, and many of his conclusions are undisputed at the present day. He is most widely known for his efforts to place human physiology on a true basis, but his discoveries in entomology and botany were no less epoch-making. His *Observationes Anatomicæ* (Bologna, 1661) contained the first published researches into the structure of the lungs with the microscope. *Epistolæ Anatomicæ* (Bologna, 1661–65) record the discovery of the *rete Malpighii*, one of the layers of the skin. His observations on the structure of the viscera and his investigations in embryology and vegetable histology, as well as his determination of the structure of glands, were equally important.

MALPIGHIA, măl-pē′gĭ-ȧ. A tropical fruit. See BARBADOS CHERRY.

MALPLAQUET, mȧl′plȧ′kȧ′. A village in the Department of Nord, France, 21 miles east of Valenciennes, and close to the Belgian frontier, celebrated for the bloody defeat of the French, under Marshal Villars, in the War of the Spanish Succession, by the troops of the Grand Alliance, under Marlborough and Prince Eugene, Sept. 11, 1709. The forces engaged consisted of more than 200,000 men, the allies having a slight superiority in numbers, but the French had the better position. The allies lost in the battle at least 20,000 men; the French not more than 15,000. The result of the conflict was the capture of Mons and Douai. See SUCCESSION WARS.

MALPRAC′TICE. In law, bad professional treatment, as of disease, pregnancy, or bodily injury, resulting from ignorance, carelessness, or done with criminal intent. In offering his services to the public the doctor or surgeon impliedly contracts that he possesses and will employ reasonable skill and learning, will exercise reasonable and proper care, and exert his best judgment to effect good results. This obligation rests on any person making a pretense of professional knowledge. Failure to do this renders him liable for resultant injuries to the patient, criminally or by civil suit, according to the degree of his negligence and fault.

Criminal liability arises from gross negligence or from incompetency. Where the results of a physician's fault are not so serious as to constitute an offense against the public and render him liable criminally, he may still be obliged to make compensation to the patient for the damages resulting from his wrongful acts through an action at law. But a physician is not an insurer, and in the absence of express agreement he does not warrant a cure, nor is the test to be applied to his performance that of the highest order of skill and care obtainable, but that of the average of members of his profession in good standing in similar localities, considering the state of medical science of the time. Thus the requirement in knowledge or skill imposed upon the frontier surgeon is not that of the attending physician of a great city hospital. His responsibility before the law is not fixed by the recognition of the tests of any particular school, homœopathic, allopathic, or empirical. What is reasonable care must be determined by the particular case, though the same degree must be rendered to the poor of the charity hospital as to the millionaire's child. This obligation to use proper diligence, care, and skill includes not only diagnosis and the employment of such obtainable remedies and appliances as discovery and experience have proved most beneficial, but also the giving of proper instructions to patients and nurses and freedom from error in writing.

On undertaking a case the law implies a contract that the physician continue his attendance while treatment is required, unless terminated by discharge by the patient or his withdrawal from the case on proper notice. When he informs a patient that his disease or injury is curable when he knows it to be incurable or is ignorant as to the truth of his representation, and the patient is induced to undergo his treatment thereby, he is liable in an action for deceit. Such misrepresentation will also be a defense to a suit on his part to recover his fees. Where a practitioner possesses the requisite qualifications and applies his skill and judgment with ordinary diligence he will not be held responsible for an honest mistake or error of judgment in diagnosis or treatment where there is reasonable doubt as to the course to be followed.

Malpractice by a lawyer is evil practice in a professional capacity and the resort to methods and practices unsanctioned and prohibited by law. Consult the authorities referred to under TORT.

MALSTATT-BURBACH, mȧl′shtȧt-bṳr′bäG. A town in the Rhine Province, Prussia, on the Saar, opposite Saarbrücken. It has extensive iron and steel works, one institution employing 4200 men, manufactures of Portland cement, machinery, railway carriages, boilers, safes, bricks, and phosphate, and is the centre of a large coal-mining district. It has considerable export trade by river in coal, ore, and limestone. Pop., 1900, 31,200; 1905, 38,554. Malstatt-Burbach was made a city in 1875, when Malstatt and Burbach were consolidated.

MALSTRÖM, mȧl-strēm′ (from Norw. *malstraum*, from *mala*, to grind + *straum*, stream), or MAELSTROM. A rapid tidal eddy or current running between Vaerö and Moskenaesö, two of the Lofoten (q.v.) Islands, lying near the southwest end of the group (Map: Norway, E 3). It has been made famous by the exaggerated accounts of older writers on Norway. Owing to the great difference in tide level in the West Fiord, between Lofoten and the mainland and the ocean, the vast mass of water, which every 12 hours must be moved from the fiord into the ocean and back again, has to run very swiftly through the narrow channels between the islands, causing in several places dangerous currents. The swiftest of these is the Moskōström, which is rendered still more dangerous by the eddies (*malströmme*) caused by sudden differences in the depth of the channel. When the current flows fastest, between high and low tide, and the wind blows directly against it, the sea for miles around becomes so violently agitated that small vessels cannot live in it.

MALT. See BARLEY; BEER; BREWING.

MALTA, mạl′tȧ. A British island colony in the Mediterranean Sea, consisting of the island of Malta (in lat. 35° 53′ N. and long. 14° 31′ E.), the neighboring islands of Gozo and Comino, and the islets Filfla and Cominotto. The distance to the nearest point of Sicily is about 58 miles and Africa about 180 miles (Map: Italy, E 7). The total area of the colony is about 118 square miles. The island of Malta is about 17 miles long and 9 miles broad, with an area of 91.6 square miles; Gozo has an area of 25.8 square miles, Comino about 1 square mile. The surface of the island of Malta is comparatively low, the highest point not exceeding 845 feet. The climate is mild and healthful for most of the year, but in summer it is hot and during August and September the sirocco prevails. The mean temperature is 64.6° F. and the mean annual rainfall 20 inches. There are no streams, the water being absorbed in the porous sandstone beds. The soil is exceedingly fertile and highly cultivated, producing two and sometimes three crops annually. The products include potatoes, corn, oranges, figs, onions, grapes, cummin seed, and honey. There are quarries of marble, alabaster, and building stone. Among the manufactures are cotton goods, filigree, lace, and matches. Many of the inhabitants are employed in connection with the trade of Valletta (the capital) as a coaling station, port of call, and entrepôt. Imports and exports of merchandise in the fiscal year 1912 were valued at £2,413,687 and £750,422 respectively; in 1913, £2,614,566 and £977,656 (in 1913, £1,129,799 from and £45,895 to the United Kingdom). The total net tonnage, exclusive of the coasting trade, entered and cleared at Valletta increased from 7,566,763 (4,981,204 British) in the fiscal year 1908 to 10,398,948 (5,510,556) in 1913. Valletta is a port of registry and had Jan. 1, 1913, 99 vessels of 4121 tons gross. There are a metre-gauge government railway of 7¾ miles; telephone, 780 miles of wire; direct cables to Alexandria (3), Gibraltar (3), Bône (2), Messina (1), Tripoli (1), Sicily (1), Zante (1). Malta, notwithstanding its small size, is of great importance to the United Kingdom on account of its strategic position in the Mediterranean. Valletta is a strongly fortified naval station on an excellent harbor. A new breakwater was constructed there in 1909.

The government is administered by a governor advised and assisted by an executive council, established in 1881, reconstituted in 1887 and again in 1903 and 1909. The council now (1914) consists of 11 official and two unofficial members besides the president. Legislation is effected by a partly elective council of government, originally constituted in 1849 and reconstituted in 1887 and 1903. It consists of 10 official members and eight elected, besides the president and vice president. The Governor is president of both councils. The colony has no direct taxation. The most important sources of revenue are customs, stamp duty, port dues, and rents. In the fiscal year 1908 revenue and expenditure were £438,348 and £445,669 respectively; in 1913, £442,035 and £427,581. Public debt, £79,081.

The people of Malta are mostly of the Mediterranean race. Many resemble the southern Italians, while some show distinct traces of Punic descent. They are industrious and thrifty. Many Maltese may be found in Algeria, Tunis, Egypt, and Gibraltar. The Maltese language, which is generally spoken, is supposed to be derived from the Carthaginian and Arabic; about 70 per cent of its vocabulary is Semitic, but the grammatical structure is derived from the Latin. The educated and commercial classes speak also Italian and English. Italian is the official language of the courts, but parents may decide whether their children shall learn Italian or English at school, and in 1912–13 over 98 per cent chose the latter. There are 172 public elementary schools, with about 21,200 pupils enrolled in 1912; two secondary schools (about 220 students), a lyceum (550), a university (165), and several other educational institutions; in addition there are about 70 private schools, with over 4000 pupils. The religion of the people is Roman Catholicism. The population in 1829 was 114,236; in 1873, 145,605. The 1901 census returned a civil population of 184,742; 1911, 213,395; 1913 (estimate), 216,617. The population, including British troops and their families present, was 228,534 in 1911. The chief town, Valletta, had with its suburbs (Floriana, Sliema, and St. Julian's) 44,143 inhabitants in 1911; "Three Cities" (Senglea, Cospicua, and Vittoriosa), 26,551; Città Vecchia, the old capital, in the interior of the island, 8896 (with suburbs); Victoria, the chief town of Gozo, about 5660. Birth rate (1912–13), 32.20; death rate, 19.79.

Malta has been identified with the Hyperion or Ogygia of Homer, the island on which Calypso (q.v.), the daughter of Atlas, who enslaved Odysseus, dwelt in a grotto. Two grottoes on Malta bearing her name are rivals as the traditional haunt of the nymph. At a very early date Malta was colonized by the Phœnicians. There are numerous remains of a still earlier people, whose culture is that of a race which once controlled the whole western part of the Mediterranean; this race too, it has been thought, came from Africa. The remains of this race consist of megalithic monuments of the neolithic period. Relics of the Phœnicians are seen in ruins of tombs, towers, houses, and cisterns. Malta had developed considerable commercial importance when about 736 B.C. the Greeks dispossessed the Phœnicians and named the island Melita. The Greeks in turn were displaced by the Carthaginians about 500 to 480 B.C. During the first Punic War Atilius Regulus, commanding a Roman fleet, ravaged the island, and in 218 B.C., during the Second Punic War, it was surrendered to Titus Sempronius by the Carthaginian commander Hamilcar, and became politically attached to Sicily. The Romans made the island a *municipium* and allowed the Carthaginian inhabitants to remain. Under the Romans, as is clear from remains of Roman houses and palaces, the island long flourished greatly. There are remains of a theatre, temples, and other buildings erected by the Romans, to whom Malta became well known for its textiles. In 61 A.D. St. Paul was shipwrecked on the north coast (see Acts xxvii and xxviii); St. Paul's Bay, in which, on the island of Selmun, is a colossal statue of the Apostle, is pointed out as the generally accepted landing place. On the dissolution of the Roman power Malta was occupied successively by Vandals in 454, by Goths in 464, and again by the Greeks under Belisarius in 533. At their third attempt during the ninth century, with the assistance of the natives who massacred the Byzantine garrison, the Arabs became the masters and fortified the harbor as a station for their corsairs in 870. They were not driven out until 1090 by the Normans under Count Roger, who established a popular form of government which, with certain modifications, lasted for 700 years. Again it became politically attached to Sicily until 1530, when Emperor Charles V granted it with Gozo and Tripoli in perpetuity to the Knights of the Order of St. John of Jerusalem, after the Turks had captured their great stronghold at Rhodes. Taking the title of the Knights of Malta, they built immense fortifications and rendered invaluable services to Christendom in checking and chastising the Barbary pirates and in defending the island against the incessant attacks of the Turks. The most formidable of these was the siege in 1565 by the Sultan Solyman II, when the Knights, commanded by the heroic La Valette forced the enemy at the end of three months to retire with an immense loss of men. Valletta was then built and the fortifications were increased. A continual war on the Moslems was waged until 1798, when, disorganized by internecine quarrels, the Knights surrendered their fortresses to Bonaparte on his way to Egypt. Three months later, however, the Maltese revolted against the French and, assisted by Neapolitan, Portuguese, and British auxiliaries, after a siege and blockade of two years, forced the French garrison to capitulate. The inhabitants claimed the protection of England, and the status of Malta as a British dependency dates from its recognition as such by the Treaty of Paris in 1814.

Senior, *Conversations and Journals in Egypt and Malta* (2 vols., London, 1882); M. M. Ballou, *The Story of Malta* (Boston, 1893); W. K. R. Bedford, *Malta and the Knights Hospitallers* (London, 1894); F. M. Crawford, *Rulers of the South, Sicily, Calabria, Malta* (2 vols., New York, 1900); William Deecke, *Italy, Popular Account of the Country, its People, and its Institutions* (ib., 1904); Albert Mayr, *Die Insel Malta im Altertum* (Munich, 1909); F. W. Ryan, *Malta* (New York, 1910); William Hardman, *History of Malta, 1798–1815* (ib., 1912); R. N. Bradley, *Malta and the Mediterranean Race* (London, 1912), containing a bibliography. See Saint John of Jerusalem, Knights of.

MALTA, Ancient and Illustrious Order of Knights of. A fraternal and beneficial order, incorporated in America as a fraternal beneficial order in 1889. The order was composed in 1913 of one supreme commandery, which is the executive branch, five grand commanderies, and 276 subordinate commanderies, which represent a total membership in America of about 32,000.

MALTA, Knights of. See Saint John of Jerusalem, Knights of.

MALTA FEVER, or Mediterranean Fever, Rock Fever, Neapolitan Fever, Undulant Fever, etc. A disease caused by the *Micrococcus melitensis* (discovered by Col. David Bruce in 1887) and characterized by fever, profuse perspiration, constipation, pain, and swelling in joints, enlargement of the spleen, and frequent relapses. Bruce believes the infection is conveyed from the sick to the healthy by way of the alimentary canal, i.e., through contaminated food or drink, goats' milk being the medium in most cases. This affection has a wide distribution along the Mediterranean coasts. Cold sponging, antipyrine, hypnotics, the application of iodine to the painful joints, aperients, and a diet of milk and broth form the treatment desirable, with a change of climate as soon as the patient is fit to move with comfort. In 1903 Malta fever appeared in Texas, in a soldier from the Philippines, making about 12 cases in the United States, all imported. Other cases have been reported in the Mississippi valley and in the Southwest (Arizona and New Mexico), where mohair goats are extensively raised. The disease has a mortality rate of only about 3 per cent.

MALTASE, mạl′tās. See Digestion in Plants; Enzyme.

MALTE-BRUN, mäl′te-bro͞on′, *Fr. pron.* målt′brēN′, Konrad, properly Malte Bruun (1775–1826). A Danish geographer, born at Thisted, Jutland. He studied in Copenhagen and, because of sympathy with the French Revolution and bitter pamphleteering against the government, was in 1800 condemned to perpetual banishment. He sought refuge in Sweden and then in Paris, where he maintained himself by teaching and literary labors. In 1808 he began the *Annales des voyages, de la géographie et de l'histoire* (24 vols.), which he concluded in 1814, and in 1818 began, with Eyriès, the *Nouvelles annales des voyages.* For some time he was joint editor of the *Journal des Débats,* but is principally known for his geographical works, chief of which is the *Précis de la géographie universelle,* completed by Huot, eight volumes, with an atlas (Paris, 1810–29; 6th ed., 1853; new ed., 1872). He took part also in the preparation of the *Dictionnaire de la géographie universelle* (Paris, 1821 et seq.), and was secretary to the Geographical Society of Paris.—His son, Victor Adolphe (1816–89), was one of the eminent geographers of France, taught at various institutions, and succeeded his father as secretary of the Geographical Society of Paris. He published *La France illustrée* (3 vols., 1857; new ed., 1895–97), *Géographie universelle* (1874), *L'Allemagne illustrée* (1884–85), etc.

MALTEN, mäl′ten, Therese (1855–). The stage name of a noted German dramatic soprano, Therese Müller, born at Insterburg.

She studied with Gustav Engel in Berlin and made her début in 1873 in Dresden as Pamina in *The Magic Flute.* From that time on till her retirement in 1903 she remained a member of the Dresden Opera, with frequent leaves of absence for appearances in the principal European opera houses. In 1882 Wagner conferred upon her the honor of selecting her as the original Kundry in *Parsifal.* Her repertory included all the great operas, but she was preëminent as an interpreter of Wagner's heroines.

MALTESE, ma̤l-tēz′ *or* ma̤l-tēs′. The name of a breed (1) of cats and (2) of lap dogs. The Maltese or blue cat is so called on account of its uniform bluish-gray color. (See Cat, *Domestic Cat.*) The dog is supposed to have originated in Malta.

MALTESE CROSS. A cross of eight points, of the form worn as a decoration by the Hospitalers and other orders of knighthood. See illustrations to Heraldry.

MAL′THA (Lat., from Gk. *μάλθα*, mixture of wax and pitch for calking ships). A name originally applied to a mineral fat from Kirwan, resembling wax and probably composed of paraffin. The name is now applied to the semisolid or viscous varieties of bitumen. It is of black color, with a specific gravity of 1 or a little less. Mineral tar is a popular name for it. Maltha resembles petroleum in composition, but differs from it in containing a smaller percentage of the lighter oils. Indeed, it may at times have been formed by the oxidation and evaporation of petroleum on exposure to the air. In the United States it is found in California, where it oozes from the rocks in certain localities, but the quantity available is not large. See Bitumen; Asphalt.

MALTHUS, măl′thŭs, Thomas Robert (1766–1834). An English economist. He was educated by private tutors at his home, at a small academy at Warrington, and at Cambridge, where he received the degree of B.A. in 1788. The following years he devoted to the study of physical science, with, however, a growing interest in social problems. In 1791 he received the degree of M.A. and in 1793 a fellowship in his college, and took a curacy near Albury. The publication of William Godwin's *Enquirer*, which argued for a reconstruction of society on a basis of equal distribution of goods, inspired Malthus to a study of population, the fruit of which was the *Essay on the Principle of Population as it Affects the Future Improvement of Society* (1798), which was published anonymously. The main thesis of this work was that population in all times has tended to outrun subsistence. The means of subsistence, Malthus argued, might increase in arithmetical progression, but population tended to increase in a geometrical ratio. Accordingly there could be no permanent amelioration of the lot of the lower classes; a redistribution of wealth might bring them plenty for a time, but population would soon overtake subsistence, and would as before be kept in check by starvation or vice, unless checked by self-restraint. In 1803 a second edition of the *Essay on Population* appeared. In this edition Malthus defends his proposition by a wealth of data relating to civilized, barbarous, and savage peoples. Here as in later editions he is more disposed to dwell upon the necessity of moral restraint as a preventive of overpopulation and less inclined to regard vice and misery as the fate of the human mass.

The importance of this work for economic thought can hardly be overestimated. Before the publication of the *Essay on Population* it was held even by statesmen like Pitt that increase in population is always an unqualified advantage for a state. The arguments of Malthus quickly dispelled this belief and served to direct public sentiment against a poor law that was rapidly filling England with paupers. In economic science the "Malthusian doctrine" has played an important part in every theory of wages propounded since its enunciation; and in a widely different department of thought—biology—the work of Malthus has the distinction of having suggested to Darwin the influence of the struggle for survival upon progress.

In 1805 Malthus was appointed professor of political economy at the East India Company's College at Haileybury. He entered upon his duties there in 1807 and occupied that position until his death. Of his other works, the *Nature and Progress of Rent* ranks high among the original contributions to political economy. In this essay the "law of diminishing returns," afterward identified with the name of Ricardo, is stated with great clearness. Little of importance was added by his *Political Economy* (1820) and by his numerous economic pamphlets.

No economic writer has been more harshly criticized than Malthus. "Malthusianism" still designates an attitude of hard-hearted indifference to the sufferings of the poor. Because of the extravagance of some of his followers, the Neo-Malthusians, who sought to popularize artificial methods of checking the growth of population, Malthus has frequently been denounced as an exponent of immorality. His *Essay on Population* has received numberless "refutations," but scientific economists are agreed that when divested of its too absolute form of expression, the doctrine of Malthus enunciates an indisputable truth, which cannot be ignored with impunity by any plan of social amelioration or reform. See Political Economy.

Bibliography. The best work on Malthus is James Bonar, *Malthus and his Work* (New York, 1905). Consult also H. Soetbus, *Die Stellung der Sozialisten zur malthus'schen Bevölkerungslehre* (Berlin, 1886); David Ricardo, *Letters to Malthus, 1810–1823* (Oxford, 1887); De Molinari, *Malthus, essai sur le principe de population* (Paris, 1889); S. N. Patten, *Malthus and Ricardo* (Cambridge, Mass., 1889); F. Fetter, *The Essay of Malthus* (1898); Lujo Brentano, "The Doctrine of Malthus and the Increase of Population during the Last Decades," in *Economic Journal*, vol. xx (London, 1910); C. V. Drysdale, *Small Family System* (New York, 1914).

MALTING. See Brewing.

MALTOBIOSE. See Sugars.

MALTON, ma̤l′ton. A market town in the North Riding of Yorkshire, England, on an elevation on the Derwent, 21 miles northeast of York (Map: England, F 2). It has foundries, agricultural implement works, and large stables and training schools for race horses. It has a grammar school, founded in 1545, and the remains of a priory, founded in 1150. Pop., 1901, 4758; 1911, 4822. Malton, called by the Romans *Camulodunum*, was an important Roman military station. The town was burned and rebuilt in the reign of Stephen, after which it was generally called New Malton. About 4 miles from Malton is Castle Howard, a famous building by Vanbrugh, standing in its own park.

It is the seat of the earls of Carlisle and contains a fine chapel and a renowned collection of paintings.

MALTOSE. See SUGARS.

MALT SPROUTS (AS. *mealt*, OHG. *malz*, Ger. *Malz*, from AS. *meltan*, *miltan*, to melt; connected with Gk. *μέλδειν*, *meldein*, to liquefy, OChurch Slav. *mlŭdŭ*, soft, and ultimately with OHG. *smelzan*, Ger. *schmelzen*, Eng. *smelt*). The sprouts or radicles of germinated grain, separated before the malt is used, and also the exhausted grain residue; a by-product from breweries, resulting in the preparation of malt from barley. The barley is sprouted to develop the principle of malt in the grain, and when the process has proceeded far enough it is checked and the sprouts are broken off. The sprouts and the brewers' grain are fed to cattle and parts of the refuse are sometimes used as fertilizers. The average percentage composition of malt sprouts is: water, 10.2; ash, 5.7; protein, 26.2; fibre, 11.7; nitrogen-free extract, 44.5; and fat, 1.7 per cent. See BREWING.

MALTZAN, mäl'tsȧn, HEINRICH, BARON (1826–74). A German traveler and ethnologist, born in Dresden. He studied law at Heidelberg, traveled in the East for his health, and familiarized himself with the habits and languages of the inhabitants of Algeria, where he lived for several years. He traveled to Abyssinia in 1857 and made a ceremonial pilgrimage to Mecca in 1860, but barely escaped with his life when he attempted to get to Medina. He then returned to the northern coast of Africa, where he made researches in Tunis and Tripoli (1867–69). He wrote: *Drei Jahre im Nordwesten von Afrika* (1863); *Meine Wallfahrt nach Mekka* (1865); *Reise auf der Insel Sardinien* (1869); *Reise in Tunis und Tripoli* (1870); and *Reisen in Arabien* (1873). He committed suicide in 1874.

MA'LUM IN SE AND **MALUM PROHIB'ITUM.** *Malum in se* (Lat., evil in itself) is a term which is applied to crimes which involve moral turpitude or wrong in their very nature, such as murder or theft. *Malum prohibitum* (Lat., prohibited wrong) is applied to offenses which are not morally wrong in their nature, but are prohibited by statute and therefore unlawful. The distinction is useful in determining proper measures of punishment. Any person may be presumed to have a moral sense of right and wrong, but may nevertheless ignorantly and unintentionally violate some statute or ordinance which does not involve moral transgression. See CRIME.

MALUS, mȧ'lụs', ETIENNE LOUIS (1775–1812). A French military engineer and physicist, born at Paris and educated at the Ecole Polytechnique. He served in the Army of the Rhine, was attached to the Egyptian expedition, was present at the siege of Cairo, and came back to France in 1801. He then took charge of the fortifications at Antwerp and Strassburg, at the same time carrying on his scientific researches. His *Traité d'optique*, published in 1811, treats of the refraction and reflection of light and contains experiments in regard to the reflection of light by transparent media. Malus in the course of his experiments discovered that the phenomenon known as the polarization of light would be produced by reflection. As he believed in the emission theory, he advanced the hypothesis that particles of light have poles and that on entering a doubly refracting crystal some of the particles forming one of the rays may be so arranged as to be transmitted through it, while the particles which should have formed the other ray may be so arranged as to prevent their transmission in certain directions. (See LIGHT.) Malus published an account of his experiments in the *Memoirs* of the Institute, which at once elected him to its membership; and the English Royal Society gave him the Rumford medal, though France and England were then at war. In 1810 he published his *Théorie de la double réfraction de la lumière dans les substances cristallisées*, which was crowned by the Institute.

MALVA'CEÆ (Neo-Lat. nom. pl., from Lat. *malva*, mallow). A family of plants including about 45 genera and 900 species, widely distributed in temperate and tropical regions. They are herbs or shrubs, sometimes becoming trees in the tropics. The family is characterized by its alternate, mostly palmately veined leaves, its regular and often large flowers, but chiefly by its monadelphous stamens, which form a central column around the pistil and are inserted with the base of the petals. The conspicuous useful plant of the family is cotton (*Gossypium*, q.v.). Other well-known genera are *Althæa* (including marsh mallow and hollyhock), *Malva* (mallow), *Sida*, *Abutilon* (Indian mallow or velvet leaf), and *Hibiscus* (including rose mallow, the shrubby althæa of gardens, and okra or gumbo).

MALVERN, măl'vẽrn. A city and the county seat of Hot Spring Co., Ark., 21 miles southeast of Hot Springs, on the Chicago, Rock Island, and Pacific and the St. Louis, Iron Mountain, and Southern railroads (Map: Arkansas, C 3). It is surrounded by a cotton, timber, and fruit-growing district and has four large lumber mills and manufactures of doors, windows, chairs, ice, and bricks. Pop., 1900, 1582; 1910, 2778.

MALVERN, mạl'vẽrn *or* mạ'vẽrn, GREAT. A town and inland watering place in Worcestershire, England, picturesquely situated on the east side of the Malvern Hills, 8 miles southwest of Worcester (Map: England, D 4). Its mean annual death rate is less than that of any other watering place in the Kingdom, owing to the purity and abundance of the spring water and the remarkable salubrity of the climate. It has chalybeate, saline, and alkaline springs and is a great summer resort. Its restored eleventh-century priory church is famous. Malvern is a great educational centre, the most prominent school being Malvern College (1865), a public school for boys. Near by are the villages of Malvern Link, Malvern Wells, Little Malvern, and West Malvern, all of them consisting of villas, hotels, and hydropathic establishments. Pop., 1901, 16,400; 1911, 16,513.

MALVERN HILL, BATTLE OF. A battle fought on July 1, 1862, at Malvern Hill, Va., near the north bank of the James River, about 15 miles southeast of Richmond, between the Federal Army of the Potomac, numbering about 80,000 men, under General McClellan, and the Confederate Army of Northern Virginia, also numbering about 80,000, under General Lee. It was the last of the "Seven Days' Battles" (q.v.) in the Peninsular campaign. After the engagements at White Oak Swamp and Glendale on June 30 the whole of the Federal army was stationed on Malvern Hill, an eminence about 60 feet in height, by nature a position of great strength. Gen. Fitz John Porter was in immediate command, General McClellan having absented himself to confer with Commodore Rodgers on the gunboat *Galena.* Late in the afternoon of the 1st the Confederates, under the immediate command of Generals D. H. Hill, Huger, and Magruder, advanced against the position, though there had been an almost continual artillery fire throughout the morning; and the fighting continued with slight intermission until nine o'clock in the evening, when the Confederates, having sustained heavy losses, finally withdrew without making any impression on the Federal lines. The Federal artillery, which proved exceedingly effective throughout the battle, and was so posted that the fire of 60 guns could be concentrated on any point, was under the general direction of Colonel Hunt. During the battle also a fire from the gunboats in the rear of the Federals did some execution in the Confederate ranks. The exact losses of the two armies at Malvern Hill were never accurately determined, but it is estimated that the Confederates lost more than 5000 in killed and wounded and the Federals about one-third of that number.

Ropes, *The Story of the Civil War*, part ii (ib., 1898); Johnson and Buel (eds.), *Battles and Leaders of the Civil War*, vol. ii (ib., 1901); P. S. Michie, *General McClellan* (ib., 1901), in the "Great Commanders Series"; Alexander, *Military Memoirs of a Confederate* (ib., 1907).

MALVOISIE (măl′vwȧ-zē) **WINE.** See Wine.

MALVOISIN, mȧl′vȯ-zĭn, or **MAWMOISINE,** mą′moi-zĭn, William (?–1238). A Scottish ecclesiastic. He was born in Normandy and educated in France. Going to Scotland, he was made one of the *clerici regis* and archdeacon of St. Andrews. In 1199 he was constituted Chancellor of Scotland, in 1200 Bishop of Glasgow, in 1202 of St. Andrews; in 1211 he resigned his chancellorship; in 1212 by appointment of the Pope he convoked at Perth a great council of the clergy and people to press upon the nation the Pope's will and command that an expedition be undertaken to Palestine, but the nobles received the proposition coldly. In 1214 he attended the coronation of King Alexander II and is said to have placed the crown on his head. The following year he went with the bishops of Glasgow and Moray to Rome to attend the fourth Lateran Council, remaining abroad until 1218. On his return he effected the deliverance of Scotland from the papal ban. He brought from the Continent various orders of monks and mendicants before unknown in Scotland, and established convents of black friars at several places. He died in Inchmurtach, near St. Andrews, July 5, 1238.

MALVO′LIO. In Shakespeare's *Twelfth Night*, steward to Olivia.

MÄLZEL, mĕl′tsel, Johann Nepomuk (1772–1838). A German inventor of musical mechanisms, born at Ratisbon. At first a music teacher, he soon became famous for his inventions, among them a sort of orchestrion, a mechanical chess player, and an automatic trumpeter. In 1808 he was made court mechanician at Vienna. He constructed a number of ear trumpets, one of which was used by Beethoven. He was credited with having invented, in 1816, the metronome (q.v.), but in this he was anticipated, probably by Winkel of Amsterdam. He died while en route for the United States.

MAM, mäm. One of the principal Mayan tribes of Guatemala. The Mam are located chiefly in the western part of the Republic, but extend likewise into the adjacent districts of Chiapas, Mexico. The name signifies "ancestral," in allusion to the archaic forms of the language.

MAMÆ′A, Julia (?–235 a.d.). A Roman lady, mother of the Emperor Alexander Severus. A niece of Septimius Severus, she was born in Emesa, Syria. She was a woman of high principle, and educated her son so well that he was a model of all virtues save generosity. Mamæa's greed and parsimony roused to revolt the soldiers, who killed her and her son. Ulpian was one of her advisers, and tradition makes her not unfriendly towards the Christians.

MAMÁNUA, mȧ-mä′nōō-ä. A Negrito people in northeastern Mindanao. See Philippine Islands; Negrito.

MAMARONECK, mȧ-măr′ȯ-nĕk. A town, including the village of Larchmont and part of Mamaroneck village, in Westchester Co., N. Y., on Long Island Sound, 21 miles northeast of Grand Central Station, New York City, on the New York, New Haven, and Hartford Railroad (Map: New York, B 2). It is popular as a suburb of New York City and as a summer resort, with good bathing and fishing facilities. It has many handsome residences. Larchmont village contains the well-known Larchmont Yacht Club, and was once the home of J. Fenimore Cooper. There are manufactures of raincoats and rubber goods and a pumice-stone mill. Pop., 1900, 3849; 1910, 5699; Larchmont, 1910, 1958. Mamaroneck was purchased from the Indians on Sept. 23, 1661, by John Richbell. The name (from the Indian) means "where the fresh water met the salt."

MAMBÁJAO, mȧm-bä′hou. A town of the Province of Misamis, Philippines, situated on the northeast coast of Camiguín Island, off the north coast of Mindanao (Map: Philippine Islands, E 6). The shore here is very rugged. Pop., 1903, 14,446.

MAM′BER. The common wild goat of southwestern Asia and Asia Minor. See Goat.

MAMBRES, măm′brēz. See Jannes.

MAMBRINO, mȧm-brē′nȯ. A pagan king of Bithynia, mentioned in old Italian versions of the Charlemagne epic and further described in Ariosto's *Orlando furioso*, in which Mambrino is killed by Rinaldo. He wore a helmet of gold, which had the power of making the wearer invisible. This helmet figures in *Don Quixote*, whose hero, on seeing a barber wear a brass basin as a hat, declared it to be the magic helmet and wore it as such.

MAMBÚSAO, mȧm-bōō′sou. A town of Panay, Philippines, in the Province of Cápiz, situated on the river Malinannang, 17 miles southwest of Cápiz (Map: Philippine Islands, D 5). Pop., 1903, 8225.

MAMELI, mȧ-mā′lė, Goffredo (1827–49). An Italian poet and patriot, born at Genoa, son of Admiral Giorgio Mameli. He wrote a tragedy founded on Genoese history, when but 16 years old, and his verses, *L'Alba* and *Fratelli d'Italia*, became the campaign songs of 1848. He served under Garibaldi as aid-de-camp and in the defense of Rome (1849) was fatally wounded. Mazzini wrote an introduction to the edition of his poems published at Genoa in 1850. The best edition is that of Tortona (1859).

MAMELUCO, mä′mȧ-lōō′kȯ. The name given in central Brazil to the half-breed offspring of whites or negroes and Indians. It evidently has reference to the Mamelukes. See GUARANÍ.

MAMELUKES, măm′ĕ-lūks (from Fr. *mameluk, mamaluc*, from Ar. *mamlūk*, purchased slave, from *malaka*, to possess). A dynasty of Egyptian sultans who ruled from 1250 to 1517. The name was originally applied to the Turkish slaves who were brought in large numbers into Egypt and came to constitute the main strength of the army, filling at the same time the highest posts in the state. In time the Mamelukes were recruited by large numbers of Circassian slaves. In 1250 the last Ayubite ruler died and the power fell into the hands of the Emir Eybek, who married Sheger ed Durr, the mother of the dead monarch. The dynasty founded by Eybek is known as that of the Bahrite Mamelukes. Eybek was murdered in 1257 by his wife, and the government was assumed by the Viceroy Kutuz, who in 1260 gained a notable victory over the Mongols, and established his power over Syria. The celebrated Bibars ruled from 1260 to 1277. He waged war against the Christians in Syria, and in 1268 put an end to the principality of Antioch. His armies overran Armenia and penetrated far into Asia Minor. His power towards the south extended as far as Nubia. Al Mansur (1279–90) carried on successful wars against the Mongols and Christians. He took Damascus and made himself master of Tripolis, which for two centuries had been held by the Christians. Al Mansur's two sons ruled in succession and increased the power of the sultanate, while at the same time the condition of the people was improved by the construction of important public works. Cairo was greatly beautified and rose in importance as one of the capitals of the East. There followed a period of steady decline during which the real power passed from the hands of the sultans to the commanders of the troops, which were now largely composed of Circassians. In 1389 the last Bahrite ruler was deposed and Barkuk, first of the Circassian or Burji Mamelukes, ascended the throne. During the reign of Barkuk Egypt was threatened by the power of Timur, who wrested from Barkuk's son, Faraj, a great part of Syria. Barsa Bey (1422–37) reduced Cyprus to the position of a vassal state and exercised considerable influence in the eastern Mediterranean. Kait Bey (1468–96) carried on war against Sultan Bajazet II in support, partly, of the claims of the latter's brother, Jem. After Kait Bey's death five sultans ruled within as many years, most of them perishing by assassination. In 1501 Kansuh el Ghuri was raised to the throne. After reigning for 15 years he engaged in war with the Turkish Sultan, Selim I, and was overthrown and slain in a sanguinary battle at Marj Dabik, near Aleppo (1516). The Mamelukes under Tuman Bey II resisted the invasion of Egypt by Selim and fell in large numbers on the field or during their desperate defense of the capital. Their dynasty disappeared from the throne and Egypt became a Turkish province (1517). To conciliate the surviving Mamelukes, Selim divided Egypt into 24 military provinces and placed Mameluke beys over them subject to the supreme authority of a Turkish pasha. With the decay of the Turkish Empire the Mameluke beys arrogated to themselves greater powers and finally ruled in almost virtual independence. Napoleon encountered the Mamelukes under Murad Bey in the battle of the Pyramids, July 21, 1798, and utterly defeated them. After the expulsion of the French from Egypt the Mamelukes contended with the Turks for dominion. The ambitious Mehemet Ali (q.v.) determined to crush and exterminate this military aristocracy. On Aug. 17, 1805, more than 100 of the Mamelukes were enticed into Cairo and slaughtered. On March 1, 1811, treachery was again resorted to and about 470 Mamelukes were shot down in the citadel at Cairo. This was followed by a general slaughter of Mamelukes all over Egypt. A remnant of them fled to Nubia, where they were followed by Ibrahim Pasha (q.v.), who put to death some and dispersed the rest. With their disappearance Egypt was rescued from the conditions of anarchy into which the struggle of the beys had plunged it for so many years. Consult Makrizi's history of the Mameluke sultans, translated by Quatremère (3 vols., Paris, 1837–41), and William Muir, *The Mameluke or Slave Dynasty of Egypt, 1260–1517* (New York, 1906).

MAMER′CUS. The son of Numa Pompilius, and the name of a prominent Roman family of the Æmilian gens which traced its descent to him.

MAMER′TINE PRISON, THE, called also the *Carcer Tullianum*. One of the few remains of the ancient Rome of the royal period and, next to the walls of Roma Quadrata, the earliest building extant. It is of three periods: to the earliest—supposed traditionally to be the time of Ancus Marcius—belongs the lower chamber; to the second, still in the royal or more probably the early republican era, belongs the upper chamber; to a restoration of much later date (Tiberius) is due the façade built when part of the circular chamber was cut off. The original chamber was circular, with a false pointed dome, its walls being built of large blocks set in overhanging courses. It is a matter of dispute whether this chamber was used as a well, a theory favored by the name Tullianum (from *tullus*, "a spring"), or as a royal or princely tomb, a theory favored by many analogous examples and by the absence of water corrosion. When the upper chamber was built, presumably for a prison (Livy i, 33, 8), the builders discovered the earlier building below it and made an awkward connection by cutting off the upper part of the false dome and covering the opening with flat slabs which formed the floor of the upper chamber, with a connecting trapdoor. This floor was considerably above the level of the Forum, on the declivity, and was reached by a flight of stairs called the Scalæ Gemoniæ (stairs of sighs), where the execution of important prisoners took place and their bodies were exposed during the triumphal processions before the ascent to the Capitol. The Mamertine Prison itself is connected with many of the most tragic events of Roman history. Its horrors were described by Sallust. King Jugurtha was starved in it, and Lentulus, Cethegus, and others who had conspired with Catiline were killed here. The popular tradition that St. Paul was confined here rests on no solid foundation.

MAMER′TINES (Lat. *Mamertini*, sons of Mars). The Campanian mercenaries of Agathocles (q.v.), ruler of Syracuse, hired by him to defend Messana in his interests against the Carthaginians. By 282 B.C., however, they had seized the town of Messana (see MESSINA) and were instrumental in bringing on the First Punic War. Beset both by the Greeks, led by Hiero of

Syracuse, and by the Carthaginians, the Mamertines appealed for aid to Rome. This the Senate hesitated to grant, but it was voted by the people, and war with Carthage followed. Consult E. S. Schuckburgh, *History of Rome* (London, 1894).

MAMERTUS, Claudianus. See Claudianus Mamertus.

MAMIANI, mȧ-myä′nė̂, Terenzio, Count Della Rovere (1799–1885). An Italian writer, philosopher, and statesman, born at Pesaro. From boyhood a patriot, he was concerned in the revolt that followed the accession of Gregory XVI, was captured by the Austrians, and after a short imprisonment went to France. Upon his return to Italy in 1847 he held the post of Minister of the Interior under Pius IX from May to August, 1848. He then went to Turin, where he founded with Gioberti the Society for the Advancement of Italian Unity. He was recalled to Rome, and after the flight of the Pope took the portfolio of Foreign Affairs under Galetti, but held it only for a few weeks. When the French took the city in 1849 Mamiani retired to Genoa, where he established the Academia di Filosofia Italica. He was elected Deputy from Genoa in 1856, and later Cavour gave him the post of Minister of Public Instruction (1860). Here he left a strong influence on the future of Italian education. Afterward he was made Minister to Athens in 1861 and to Bern in 1865. He was also professor of history and philosophy at the University of Turin and editor of *La filosofia delle scuole italiane*. Mamiani's intellect embraced and penetrated to some depth all the principal problems of Italian thought, art, politics, and religion during the reconstruction period of the nineteenth century. His work, although too diffuse to rank preëminently in any one field, is profoundly characteristic of his time. In criticism he was a Manzonian, in politics a stanch supporter of Cavour; in philosophy, at first an empiricist, he ultimately modified his views to conform more nearly with the idealism of Rosmini and Gioberti. All his work is colored with the nationalistic impulse of the Italian *Risorgimento*. His works include: *Poesie* (1857); *Del rinnovamento della filosofia antica italiana* (1834); *Dialoghi di scienza* (1848); *Le confessioni di un metafisico* (1865); *D' un nuovo diritto Europeo* (1859); *Psicologia di Kant* (1877); *La religione dell' avvenire* (1879); *Critica delle rivelazioni* (1880). Consult Mestica, *Poesie e prose scelte di Terenzio Mamiani* (Castello, 1886).

MAMIL′IA GENS. A plebeian gens at Rome, originally a family of Tusculum which traced its origin to Mamilia, the daughter of Telegonus, the reputed founder of Tusculum. It comprised three families, whose cognomina were Limetanus, Turrinus, and Vitulus.

MAMMÆ′A. See Mamæa.

MAMMAL. See Mammalia.

MAMMA′LIA (Neo-Lat. nom. pl., from Lat. *mammalis*, relating to the breast, from *mamma*, Gk. *μάμμη*, *mammē*, breast). The highest class of vertebrates, which includes man, his domestic animals, and all others that suckle their young—the mammals. Mammals are warm-blooded; i.e., the temperature of the body is kept approximately at a fixed point, generally higher than that of the surrounding medium. The fixed optimum temperature differs in different mammals, but it is about 100° F.

Development and Nourishment of Young. The most distinctive character of the mammalia is their mode of development and of nourishment during the earliest period of life. Excepting only the lowest forms (Prototheria), all are brought into the world alive, not merely by the retention and hatching of the egg within the oviduct, but by the formation of a new connection between the embryo and its mother. The minute ovum (see Embryology, Human) on reaching the uterus (or womb) connects itself by a set of rootlike tufts of vessels with the maternal vessels in the wall of the uterus. These tufts form an organ called placenta, by which the embryo absorbs nutriment from the mother's blood, and which conveys back to the mother's circulation for excretion by her the waste products of metabolism.

All mammals nourish their young (which at first are unable to digest any other sort of food) upon milk (q.v.), a richly nutritious fluid secreted by the mother's body in "mammary" glands, which become greatly developed in the female during the periods of gestation and lactation; and, as this is found in no other class, it is the character by which the entire group is most positively defined, and from which it derives its name. The mammary glands exist in both sexes, but, except in very rare cases, it is only in the female that they secrete milk. Their number is never less than two, and, when more, is generally nearly proportional to that of the young produced at each birth. That there is direct connection between the number of young and the number of teats has recently been shown in the case of ewes which have been bred to throw two, three, or more young at a birth. In such cases the number of teats has increased proportionately. Their position varies, being determined in each case by convenience of approach by the suckling young. In the whales, where prolonged sucking would be difficult on account of their aquatic life, the ducts of the glands are dilated to form a reservoir from which the milk is ejected into the mouth of the young by a compressor muscle of the mother. In the Prototheria (q.v.) the mammary glands have no teats, but the milk simply oozes out through numerous pores. In the marsupials the teats are well developed, but the glands are provided with special muscles by which milk is forced into the mouth of the extremely rudimentary young in the mammary pouch. The skin in the mammalia produces a covering of hair (q.v.), which is a peculiar characteristic of this group, so that it would be a sufficient definition of a mammal to say that it is an animal producing hair. In some, however, it is modified into bristles, scales, and other unusual forms, or it may be almost wholly absent, as in whales.

The general structure is typified by that of man and is abundantly described elsewhere, so that no more need be said here than a few words in reference to the cranium. Among the most characteristic points in the mammalian skull it may be mentioned generally (1) that the lower jaw articulates directly with the skull, there being no intervening tympanic bone, such as occurs in the other vertebrates; and (2) that the occipital bone of the skull articulates with the first vertebra by two condyles, one on either side of the occipital foramen, as in amphibians, instead of by a single condyle, as in the reptiles and birds. In proportion as a mammal is remote in relationship from man we find that the cranium is diminished; that the face is prolonged by extension of the jaws and nasal cavities; that the orbits are directed outward, and are less distinct from the temporal fossæ; and that the occipital foramen and condyles are placed towards the posterior part of the skull, instead of occupying the middle of its inferior surface, as in man. For further information as to anatomy and physiology, see the articles Skeleton; Teeth; and those upon the various organs and functions of the human body, with the articles on comparative anatomy accompanying them; also articles upon the various groups of mammals, as Carnivora; Ruminant; Elephant; and the like.

Mammals are very generally distributed over the surface of the globe, and the details in regard to the distribution of the various subclasses and orders are extremely interesting. Among some of the most important facts may be mentioned the absence of mammals from New Zealand and oceanic islands; the restriction of monotremes and all marsupials (except the American opossums) to Australasia; and the peculiar mammalian fauna of Madagascar. See Distribution of Animals.

With respect to their natural history, the part they play in the interrelations of the living world, and their economic service to man, a large volume might easily be written. Mammals are found under all possible conditions of life; they inhabit the air, trees, surface of the earth and subsoil, and fresh and salt water, from the equator to the poles. They thus exhibit an extraordinary variety of adaptations, and are affected by and react upon all conditions of existence. Where room is almost unlimited and food abundant and perennial, great size is attained, as in the whales, which reach a length of 100 feet and corresponding bulk and weight; elephants, which may weigh five tons; and the great grazers, which often exist in vast herds; and, on the other hand, many forms, adapted to a very limited range of vital conditions, are minute in size. Between these extremes is a wide range of size, power, and adaptability to climate and food, so that hardly any organic thing, alive or dead, escapes being eaten by some mammal. On the other hand, they themselves form the food of each other and of all other flesh-eating creatures in a greater or less degree. In respect to food the mammals fall into two great categories—vegetable feeders and flesh eaters, with a few forms that may be omnivorous. The vegetable feeders (Edentata, Sirenia, Ungulata, and Rodentia) are likely either to be of large size or exceedingly numerous in individuals, or both. They are ill provided with weapons of defense or offense; trust for safety to powers of swift escape or of skillful hiding; and as a rule are sluggish and inferior in brain power. It is their part (from the present point of view) to elaborate from the semicrude nutriment in vegetation the more compact and highly nutritious substance called flesh, which is to be used by their superiors in organization; their mission in life is to provide a prepared food for the carnivores. These qualities also make them useful to man, and it is from this class that he derives almost everything in the way of food, oil, clothing, and service which animals contribute to his welfare.

The flesh eaters include two aberrant groups—the aërial insect-catching bats and the marine Cetacea, the latter, by the peculiarities of their respective habitats and the restricted character of their food, having a special place and special functions. A few forms of antiquated organization, small size, much restricted range, and inferior abilities generally feed upon insects alone (Insectivora) or in large part (Primates), and share the perils of the vegetable eaters. The greater part of the flesh eaters, however, form a group (the order Carnivora) which in complexity of organization, power, resourcefulness, and general ability stands at the head of the animal kingdom. Whatever may have been the case with the extinct and unknown ancestry of man, there is no question that the cats and weasels and their kin are far superior even to the anthropoid apes in those powers and abilities which make for mastery in the animal world. These remarks have applied mainly to the eutherian mammals; but a similar division is found in the Metatheria (marsupials); and this circumstance is an argument in favor of the theory of the independent origin and development of that group, and opposed to the view which regards it as a stage in the evolution of the mammalian stock. In both groups the vegetable feeders are numerous, large, timid, comparatively defenseless, and without either means or desire for aggression, except as between males of the same species. They get their food with comparatively little exertion, and, except in the case of certain rodents, have had occasion to develop few instincts or mental faculties. Their whole life is passed in an effort to escape by fleetness or to find and keep a hiding place; and here mainly have been developed such devices as illustrate protective coloration and mimicry (q.v.) in this branch of the animal kingdom.

The carnivores, on the other hand, have been compelled to work day by day for their subsistence. They have been obliged to overcome by strategy and cunning, as well as by force, the greater size and speed of many of the vegetable eaters, and to oppose quickness, patience, and wit to the numberless defensive and protective abilities and devices of the smaller and more secretive animals; and they have been forced to do this in close and constant competition with other carnivores. Hence the apparatus of claws and carnassial teeth, developing the canines rather than the incisors; the tireless, efficient muscles; the capability of sudden tremendous exertion and equally of great endurance; the vigilance, courage, subtlety, and resourcefulness which characterize cats, wolves, foxes, dasyures, weasels, and lesser beasts of prey. Developed by such a history of contest and courage, it is not strange that ferocity and self-reliance should characterize the disposition of the carnivores, nor that mankind in its progress towards peace has found itself in competition with them for the possession of the best of their prey—the edible herbivores—and also at war with them for its own defense. It is wonderful, however, that man should have derived from this class such friends and helpers as the cat and dog, and no stronger evidence could be adduced in favor of the proposition that the Carnivora represent the highest animal mental development than the tractability of the dog and cat and the mental qualities they have exhibited under man's control and tutelage.

MAMMALS OF EARTH, AIR, AND WATER

Classification. Linnæus (1766) divided the mammals into seven orders: Cete, Belluæ, Pecora, Glires, Feræ, Bruta, Primates. Of these orders the Cete, Glires, and perhaps Belluæ and Pecora were natural groups quite similar to some of our modern orders. But under Feræ were grouped opossums, moles, hedgehogs, weasels, bears, dogs, cats, and seals; evidently the use of animal food was the principal character common to such an assembly. Under Bruta, moreover, such widely different animals as elephants, anteaters, and sloths were united. Finally, in the Primates, not only were man and monkeys associated, but even the bats were included. Cuvier reformed this arrangement as a result of extensive anatomical investigations. He recognized nine orders of mammals, as follows: Bimana, Quadrumana, Carnivora, Marsupialia, Rodentia, Edentata, Pachydermata, Ruminantia, Cetacea. There is little that is really unnatural in this arrangement, and it remained in popular use down to the very close of the nineteenth century. Cuvier regarded man's intellectual qualities as such as to rank him in an order apart from the monkeys, a backward step from Linnæus' arrangement. His Bimana and Quadrumana are now fused as Linnæus' Primates, and Cuvier's Pachydermata and Ruminantia are likewise united; but his other orders stand substantially as made. After the doctrine of organic evolution was generally accepted, the tendency was towards a far more elaborate and complex classification among both animals and plants. As a result, some of the proposed classifications of mammals suggested no less than 25 orders; but the pendulum soon reached its limits on that side, and we are now far nearer a natural classification than we have ever been previously. It is generally agreed now that the class Mammalia is very naturally divisible into two subclasses, according to the arrangement of the reproductive organs and the relations between mother and offspring. The primary divisions ought to be based on such characters, for it is in just those characters that the mammals stand out in sharpest contrast to the other vertebrates. These two subclasses are known as:

1. Prototheria, or Ornithodelphia—mammals without teats.

2. Theria, or Eutheria—mammals with teats, arranged according to two plans:

a. Metatheria, or Didelphia.

b. Eutheria (proper), or Monodelphia.

In the Prototheria the female reproductive organs resemble those of birds. There is no vagina, the oviducts opening separately into the cloaca, and the uteri are merely enlargements of the oviducts. The eggs contain much yolk, are supplied with albumen and covered with a shell as in reptiles and birds. They are laid in a nest at the end of a burrow and are hatched very soon, possibly in 24 hours. The mammary glands have no teats, any part of the longitudinal depression along the centre of the abdomen (the primitive pouch) serving that purpose when the sucking mouth of the young one is applied to it. This group contains but one order of living mammals, Monotremata.

The Theria are mammals in which the mammary glands are provided with teats, and there is a more or less perfect allantoic development. These two facts, especially, have led zoölogists to join into a single group the Metatheria and Eutheria, hitherto regarded as separate groups of coördinate rank with Prototheria. These groups are thus distinguished:

In the Metatheria (Didelphia of early authors) the oviducts of the female are united in a longer or shorter part of their length, and there is no cloaca, though the urogenital and anal openings are surrounded by common sphincter muscle; each oviduct possesses a well-formed uterus. There are thus two uteri, whence the name Didelphia. The eggs of the Metatheria have little yolk and no shell. They lie in the uteri without becoming very firmly united to the walls, in some species not at all; in others, however, there is formed quite a distinct placenta. (The foregoing groups have been called Aplacentalia.) But the young remain in the uteri only a short time; even in the giant kangaroo, the largest of the subclass, they are born on the thirty-ninth day. When born, they are transferred by the mother to her pouch, where each one is placed on a teat, to which it clings automatically. This interesting subclass, like the preceding, contains but one order, the Marsupialia (q.v.).

The Eutheria comprise all the remaining (higher) mammals. In these the marsupium is absent, the vagina is fully formed and single, and there is only one uterus. The egg of the Monodelphian mammal is very minute, almost without yolk, and becomes closely connected with the wall of the uterus as soon as it enters that organ. (Hence this group has been called Placentalia.) The young develop there in closest union with the mother until their various organs are all distinctly formed and they are in condition to take milk from the mammary glands by their own efforts; but even after birth they are tended and protected by the mother. The vast majority of the 10,000 known species of mammals belong in this subclass. It has proved the dominant, the successful type. Australasia is the only land the placentals do not possess, and there geographical barriers have served to protect the marsupials from being crushed by their successful rivals. The classification of Eutheria is not easy to agree upon, but the following outline is that of Parker and Haswell (see CLASSIFICATION OF ANIMALS):

SUBCLASS EUTHERIA

Section I. *Metatheria.*
  Order Marsupialia—Marsupials.
Section II. *Eutheria vera*—Higher mammals.
  Order 1. Edentata—Edentates.
  Order 2. Cetacea—Whales, dolphins, etc.
  Order 3. Sirenia—Manatees, dugongs, etc.
  Order 4. Ungulata—Hoofed mammals.
  Order 5. Carnivora—Beasts of prey.
  Order 6. Rodentia—Rodents, or gnawers.
  Order 7. Insectivora—Insectivores.
  Order 8. Chiroptera—Bats.
  Order 9. Primates—Man, apes, and lemurs.

Still more recently several authors, Osborn (1910), Gregory (1910), and Scott (1913), have published classifications of the Mammalia including extinct forms. The following expresses the latest ideas on general ordinal relationships existing between mammals living on the earth today:

SUBCLASS EUTHERIA

Infraclass DIDELPHIA.
  Order *Marsupialia.*

Infraclass MONODELPHIA.
Cohort UNGUICULATA. Clawed mammals.
Order *Insectivora.*—Insect-eating mammals.
Order *Dermoptera.*—The flying lemur.
Order *Chiroptera.*—Bats.
Order *Carnivora.*—Beasts of prey.
Order *Rodentia.*—Gnawing mammals.
Order *Edentata.*—Sloths, hairy anteaters and armadillos.
Order *Pholidota.*—Scaly anteaters.
Order *Tubulidentata.*—The aard-vark.
Cohort PRIMATES.—Mammals with nails.
Order *Primates.*—Lemurs, monkeys, and man.
Cohort UNGULATA.—Hoofed mammals.
Order *Artiodactyla.*—Even-toed hoofed mammals.
Order *Perissodactyla.*—Odd-toed hoofed mammals.
Order *Proboscidea.*—Elephants.
Order *Sirenia.*—Sea cows and dugongs.
Order *Hyracoidea.*—Conies.
Cohort CETACEA.—Whales, dolphins, porpoises.
Order *Odontoceti.*—Toothed whales, dolphins, porpoises.
Order *Mystacoceti.*—Whalebone whales.

Fossil Mammalia. Most of the mammalian orders of modern times can be traced back to an early Tertiary period, but before then only scattered synthetic or generalized types are known. In the late Paleozoic (Permian) and the earliest Mesozoic (Lower Triassic) rocks are found remains of the so-called Theriodontia (see REPTILE), which possess characters remarkably mammalian in expression. These late, highly specialized reptiles are probably related to the rootstocks from which the most primitive ancestral forms of mammals of the Triassic and Jurassic were evolved. The known mammals of the early Mesozoic were of very small size, not larger than rats, and, as they are known chiefly by their jaws and teeth alone, some of which are of very primitive type, while others are of aberrant types, they can with difficulty be assigned to any of the later groups of the class. A few of these fragmental remains can scarcely be distinguished as either reptiles or mammals, for their teeth show characters which are possessed both by certain theriodont reptiles and by the undoubted early mammals. Such forms are *Dromatherium* and *Microconodon* of the Upper Triassic of North America. The principal genera of supposed prototherian mammals (archaic Monotremata) are *Microlestes* of the European Upper Trias, *Tritylodon* of the Karoo formation of South Africa, and *Stereognathus* of the English Lower Jurassic, *Plagiaulax*, *Bolodon*, *Ctenacodon*, *Ptilodus*, and *Polymastodon*. These are known mostly from small jaws containing a pair of ratlike incisor teeth, several premolars, of which the hindmost is the largest, and the outer edges of which are marked by oblique furrows (see illustration under DUCKBILL), and finally two to four small molars. These molars are multituberculate, and hence the above-mentioned genera are grouped in an order called Multituberculata or Allotheria. A well-preserved skull of a multituberculate (*Ptilodus*) of the Basal Eocene of Montana has raised the question whether the whole group should be regarded as early offshoots of the Monotremata or as aberrant marsupials. The other order of prototherian mammals, the modern Monotremata, is separated from the first order by almost the entire space of Tertiary time. One of these creatures, the duckbill, though toothless in its adult state, may betray its origin from a multituberculate ancestor by having in its younger stages of growth broad flat teeth which are somewhat like those of the Multituberculata.

The second subclass of primitive mammals, the Metatheria, comprises a single order, the Marsupialia, and this is divided into two suborders. The more primitive Polyprotodontia are characterized by the presence of four or five incisor teeth on each side in each jaw, and include the majority of Mesozoic mammals of Europe and North America; also the opossums (Didelphidæ), which are known first in the Laramie (Upper Cretaceous); the carnivorous marsupials (Dasyuridæ) of Australia, which can be traced back only into the Pleistocene; the bandicoots (Peramelidæ) of Australia; and the banded anteaters (Myrmecobidæ), of which no early fossil forms have been found. All these are animals of comparatively small size, and they present various adaptations of the marsupial type to particular conditions of existence. The most important Mesozoic genera of supposed Polyprotodontia are *Phascolotherium*, *Amphitherium*, *Amblotherium*, *Triconodon*, *Dryolestes*, and *Spalacotherium*, and several others chiefly from the Upper Jurassic rocks of England and Wyoming. The remaining suborder of Metatheria, the Diprotodontia, is characterized by the presence of two large incisor teeth in each jaw, and its fossil and recent forms are almost wholly confined to Australia. This suborder contains the gigantic *Diprotodon*, its smaller ally *Nototherium*, and the peculiar "pouched lion" of Owen (*Thylacoleo*), all extinct and found in Pleistocene deposits; also the modern wombats, kangaroos, and phalangers, fossil forms of which have been found in the superficial deposits of Australia and South America. The geological record of the history of the Mammalia during the whole Mesozoic is exceedingly imperfect, which is the more to be regretted as during the Jurassic and Cretaceous periods the ancestors of the existing orders were already in course of differentiation; so that in the Eocene epoch, when the record becomes fairly satisfactory, the modern orders were already established, leaving only family, generic, and minor changes during the Tertiary.

Among the Eutheria or third subclass (often called Placental Mammals) the Edentata and Cetacea are of uncertain origin. They are first known as aberrant eutherian types in the Eocene, and they present through the Tertiary degenerating series of peculiar animals. The Edentata may well represent a late Mesozoic stock. During the Tertiary they developed some odd gigantic beasts—*Megatherium*, *Mylodon*, *Megalonyx*, and *Glyptodon* (q.v.), the latter with a massive coat of armor plate. Related to these giant forms were the small ancestors of the modern sloths, anteaters, and armadillos. The Cetacea is a group of mammals which through degeneration from the normal mammalian type has become peculiarly specialized and adapted to a fishlike habit of life. The earliest form in the Eocene, *Zeuglodon*, though distinctively whalelike, has, among other characters typical of terrestrial mammals, the carnivorous type of dentition.

The hoofed mammals are known first in the lowest Tertiary deposits of North America as forms (suborder Condylarthra) that are structurally near to the earliest carnivores. These early ungulates (typified by many genera of the Lower Eocene, including *Phenacodus* from the Lower Eocene of Wyoming) have five useful toes on their plantigrade feet, and each toe has a small narrow hoof. The brain is small and slightly convoluted, and the teeth are of a generalized type with low crowns and many tubercles. From animals much resembling the primitive Condylarthra seem to have been evolved all the later and more specialized forms of ungulates. The Perissodactyla comprise the extinct Titanotheroidea, large horned animals of Eocene and Miocene time (see TITANOTHERIUM); Hippoidea, the horses and their Eocene allies the paleotheres (see HORSE, FOSSIL); Tapiroidea, including the tapirs and their extinct Eocene and Miocene allies the Lophiodontidæ; Rhinocerotoidea, the rhinoceroses, with a host of extinct ancestors reaching back into Eocene time; and the Chalicotheroidea, a peculiar group of Perissodactyla characterized by clawlike hoofs. The Amblypoda include five-toed ungulates of large size that lived during Eocene time, of which well-known genera are *Coryphodon* and *Dinoceras*. Artiodactyla, or even-toed ungulates, include the modern pigs, hippopotamus, camels, deer, cattle, etc., with long series of forms ancestral to these ranging back through Tertiary time. (See SWINE; CAMEL; HIPPOPOTAMUS; DEER; ETC.) Here also belong the extinct families: Anthracotheridæ, large animals of the older Tertiary of North America and Europe; Oreodontidæ of the Miocene and Lower Pliocene of the United States; Anoplotheridæ, medium-sized animals from the Eocene and Lower Miocene of Europe; and the Protoceratidæ of the White River Miocene of America. The ancestors of the modern elephants appear in the Upper Eocene rocks of Egypt. (See PALÆOMASTODON.) The evolution of the group during Tertiary time is manifested especially in complication of the dentition and in the development of tusks and proboscis. The Toxodontia, Typotheria, and Litopterna are suborders containing peculiar types of ungulates of uncertain affinities found in the Tertiaries of South America; and the Hyracoidea embrace only a few obscure fossil forms from Egypt and Europe. See ELEPHANT; MAMMOTH; MASTODON; ETC.

The Carnivora are known first in the Eocene with generalized carnivorous types as Creodonta (q.v.) that are akin to the early ungulates; in fact, the Creodonta is considered to be the ancestral group of both the Ungulata and the Carnivora. Eight families of creodonts are recognized, mostly from the Eocene of Europe and the United States. The more important genera are *Arctocyon, Mesonyx, Patriofelis, Hyænodon.* Some creodonts found in the Santa Cruz formation (Lower Tertiary) of Patagonia present interesting marsupial features. The true carnivores have larger, more deeply convoluted brains and strong sectorial teeth, with an accentuation of all other carnivore characteristics. The dogs, bears, weasels, civet cats, hyenas, cats, all have ancestral lines extending more or less into the early Tertiary, and some instructive phylogenetic series have been demonstrated. The marine carnivores (Pinnipedia) have not yet been surely linked with any particular terrestrial types.

The shrews and moles of Eocene time present less marked differences from their modern descendants than do any other types of mammals. Almost nothing is known of the ancestry of the bats. Among the Rodentia, the characteristic feature in the dentition, viz., the chisel-shaped incisor teeth growing from persistent pulps, is seen in fossils from the early Eocene. Such a form is *Paramys*. The hares, rabbits, rats, mice, squirrels, and beavers are known first in the Oligocene and Miocene. *Tillotherium*, often quoted as ancestral to the Rodents, is merely a rodent-like, early placental mammal.

The Primates are represented in the Eocene beds of North America and Europe by fossils which represent the Lemuroidea (e.g., *Notharctus, Adapis*), and the *Tarsius* group (*Anaptomorphus, Necrolemur*) in primitive stages. The earliest monkeys are *Homunculus* of the Miocene of Patagonia, representing the New World apes, and *Propliopithecus* of the Lower Oligocene of Egypt, representing the Old World apes, in a primitive stage. *Propliopithecus* is regarded by Schlosser as the forerunner of the group which includes the great apes and man. In the Miocene and Pliocene deposits of Europe appear apes which are closely allied to the modern genera of Africa and Asia.

The earliest-known member of the human family is the celebrated *Pithecanthropus* (q.v.) from the Pleistocene of Java; here may also be mentioned *Eoanthropus* of the Old Stone age in England, *Homo heidelbergensis*, the Neanderthal race (q.v.), and the Piltdown man. See MAN, SCIENCE OF, *Ancient Types.*

Bibliography. General works on the whole class: Cuvier and Saint-Hilaire, *Histoire naturelle des mammifères* (Paris, 1824); De Blainville, *Ostéographie des mammifères,* 4 royal quarto volumes, with magnificent plates (ib., 1839–64); T. H. Huxley, *Anatomy of Vertebrated Animals* (London, 1871); Giebel, "Säugethiere," in Bronn's *Klassen und Ordnungen des Thierreichs* (Berlin, 1874); Vogt and Specht, *Die Säugethiere in Wort und Bild*, the source of the widely copied illustrations by Specht in popular natural histories (Munich, 1883); *Cassell's Natural History,* vols. i–iii (New York, 1884); *Standard Natural History,* vol. v (Boston, 1884); Flower, *Osteology of Mammalia* (3d ed., London, 1885); Flower and Lydekker, *Mammals, Living and Extinct* (ib., 1891); Gegenbaur, *Vergleichende Anatomie der Wirbelthiere* (Leipzig, 1898); F. E. Beddard, "Mammalia," in *Cambridge Natural History*, vol. x (New York, 1902); E. T. Fauna of British India (ib., 1888–91); Hudson, *The Naturalist in La Plata* (ib., 1892); Sclater, "Mammals," vol. i, *Fauna of South Africa* (ib., 1900); Millais, *Mammals of Great Britain and Ireland*, vol. i (ib., 1905); F. C. Selous, *Hunter's Wanderings in Africa* (New York, 1907).

On fossil mammals, in addition to the well-chosen list of works cited by Woodward in *Outlines of Vertebrate Paleontology* (Cambridge, 1898), the following will be found useful: Case, "Development and Geological Relations of the Vertebrates," in *Journal of Geology*, vols. vi and vii (Chicago, 1898–99); H. F. Osborn, *Age of Mammals in Europe, Asia, and North America* (New York, 1910); and various papers by H. F. Osborn, W. D. Matthew, and Gregory in the *Bulletin* and *Memoirs of the American Museum of Natural History* (New York); by Scott, in the *Proceedings of the American Philosophical Society of Philadelphia* and the *Proceedings of the Philadelphia Academy of Natural Sciences*, and the publications by Cope and Marsh in the *Reports* of the United States Geological Surveys of the Territories (Washington).

MAMMALS. See Mammalia.

MAM'MARY GLAND. See Breast; Mammalia.

MAMMARY GLAND, Diseases of. The following are some of the most important of the affections of this gland:

Acute inflammation of the breast (*mastitis* or *mastodynia*) is characterized by great swelling, tenderness, pain, and fever. There is a knotty feeling in the inflamed part, and pus soon forms; but the abscess is often slow in pointing. The affection may occur at any period of lactation, and sometimes arises from very trifling causes—as constipation, too stimulating a diet—or more frequently is preceded by a condition known as caked breast, which in turn arises from excessive secretion with retention of milk. The bowels should at once be cleared out by sharp purgatives; fomentations should be applied; the arm on the affected side should rest in a sling; and an incision should be made to evacuate the pus. The milk should also be regularly drawn off by means of a pump, if it can be done without extreme pain. *Chronic mastitis* is an inflammation of the interstitial fibres supporting the lobules of the breast and is of importance on account of the pain and anxiety it causes and because it is often mistaken for beginning cancer. The involved parts are hard and nodular, and tender to the touch. The affection is most common at the menopause, but may occur earlier and be associated with disorders of the menstrual function. Treatment is unsatisfactory. It is of first importance that a diagnosis be made for cancer, and the patient should be frequently examined to make sure of this.

Sore nipples are a frequent cause of the preceding disease. Among the remedies for excoriations, cracks, fissures, and ulcerations of the nipple, which cause great pain in suckling, are the application of strong astringent lotions (tannin lotion, *e.g.*), touching the sore point with solid nitrate of silver (lunar caustic), and especially the application of collodion. In bad cases a metallic shield must be placed on the nipple to protect it from the clothes and from the child's mouth. The regular application of alcohol and olive oil in equal parts will sometimes prevent this affection.

The mammary gland is also liable to hydatid disease, to tumor, cyst, cancer, galactocele, galactorrhœa (excessive flow of milk). See Hydatid; Tumor.

MAMMEE (măm-mē') **APPLE** (Haitian *mamey*, the native name), *Mammea americana*. A highly esteemed fruit of the West Indies (where it is sometimes called the wild apricot) and tropical America, produced by a beautiful tree of the family Guttiferæ, 60 to 70 feet high. The fruit is roundish, from the size of a hen's egg to that of a large orange, with a thick, leathery rind, and a very delicate inner rind adhering closely to the pulp. This inner rind must be carefully removed on account of its bitter taste. The pulp is firm and bright yellow, with a peculiarly sweet and very agreeable taste and a pleasant aromatic odor. A similar fruit is produced by an African species, *Mammea africana* (called *Ochrocarpus africanus* by some botanists). The wood of the mammee apple, which is fine-grained, is very valuable for cabinetwork, and, on account of its durability when exposed to moisture, is highly prized. A liquor is distilled from the flowers, which have been first steeped in spirits of wine. There are about half a dozen species of the genus *Mammea*, all of them tropical.

MAMMI'TIS (Neo-Lat., from Lat. *mamma*, breast), Mastitis, Garget, or Inflammation of the Udder. The cattle disease ordinarily known as garget is common in well-nourished cows which are heavily fed at the time of calving. It is especially frequent in heavy milkers. In such cows a slight congestion of the udder is normal at calving time. This physiological condition may be aggravated by exposure to cold air or by neglect to milk regularly for a day or two. The udder then becomes very hot and the milk shows clots and streaks of blood. If these symptoms are not relieved, a general fever condition may be established with a cessation of milk secretion and formation of abscesses in one or more quarters of the udder. In treating the disease, the milk should be frequently drawn and the udder should be thoroughly rubbed with some ointment, such as a mixture of vaseline, gum camphor, belladonna, and henbane. Where the udder is very hard, an ointment made of one dram each of iodine and iodide of potash in four ounces of vaseline may be used. Until recovery takes place the diet should be light, and laxatives, such as Epsom salt, should be administered. Another form of the disease is known as contagious mammitis and is due to infection by a streptococcus. The symptoms are similar to those of garget. Goats are affected by a similar disease known as gangrenous mammitis, which is due to a micrococcus. Treatment of contagious forms of mammitis does not differ from that of the simple form, except that sodium hyposulphite should be given by mouth and antiseptics applied locally. Good results have been obtained by thoroughly blistering with biniodide of mercury and cantharides. Tuberculosis of the udder is frequently mistaken for simple garget. Suspected cases should be tested with tuberculin, since the milk of such cows is dangerous.

MAM'MON. An aramaic word meaning "riches." It is employed in two ways in the New Testament: (1) in Luke xvi. 9–11, where it signifies literally riches; and (2) in Matt. vi. 24 (Luke xvi. 13), where it is used for the god of riches. The phrase "mammon of unrighteousness" also occurs in the Book of Enoch (lxiii. 10) in allusion to Luke xvi. 9. It is not to be concluded, however, that there was a Syrian god named Mammon. The derivation is uncertain, and none of the explanations proffered is satisfactory.

MAM'MOTH (from Russ. *mamantŭ*, mammoth, from Tatar *mamma*, earth; so called because the Yakuts and Tungusians believed that the mammoth burrowed like a mole, since its remains were discovered underground). The woolly elephant (*Elephas primigenius*), the best-known and one of the most recently extinct of fossil elephants, closely related to the existing Asiatic elephant. (See ELEPHANT.) It inhabited central Europe during glacial and postglacial times. At that time the area of the present North Sea was forested land, and thousands of mammoth teeth and bones have been dredged from the sea by fishermen. It may have originated thereabout and moved eastward, for remains have been found throughout Asia; and it passed on by the then existing land connection with Alaska into North America, where it spread over the continent as far south as the central United States. A second species (*Elephas columbi*) has been named from some large bones found in the Southern States. The distinction between these elephants and the more familiar mastodon (q.v.) must be kept clear: the latter was a very different animal.

Though the enormous bones of these and other fossil elephants, and their almost imperishable teeth, have frequently come to light ever since the forgotten antiquity when they were hunted by primitive man, and have been the bases of strange tales, theories, and superstitions, little was known about them until the discovery at the close of the eighteenth century of remains entombed in the ice cliffs of the Siberian coast, where complete animals have been kept in cold storage for unnumbered thousands of years. These and other remains enable us to reconstruct more exactly than in the case of any other fossilized creature the proportions and aspect of this animal. Though the tradition of the marvel which the bones seemed to our forefathers has given to the word "mammoth" a sense of something huge, this elephant probably did not on the average much exceed in size African elephants of the present day. One of the largest known examples—that preserved by the Chicago Academy of Sciences—did not exceed 13 feet in height at the shoulder and had tusks 9 feet, 8 inches long. African elephant tusks 10 feet, 3½ inches long were exhibited in New York in 1900. The largest mammoth tusks ever actually measured, according to Lucas, were two from Alaska, one 12 feet, 10 inches long, weighing 190 pounds, and the other 11 feet long, weighing 200 pounds. Modern African elephant tusks of the same size would weigh 20 per cent more.

HEAD OF A MAMMOTH.

In general form and osseous structure the mammoth resembles the Indian elephant, but the skull differs in the narrower summit, narrower temporal fossæ, and more prolonged bony sheaths supporting the base of the tusks, which were long, comparatively slender, and described a curve both upward and outward. There are great variations in the amount of this curve, from almost straight to a nearly complete spiral, but it is characteristic of the species. Flower says that tusks were doubtless present in both sexes. The molar teeth are peculiar in the great relative breadth of the crown and the narrowness, close approximation, and thinly enameled walls of their transverse ridges. Outwardly the mammoth differed from any other known elephant in the fact that it was clothed with long hair and a dense, woolly underfur, in adaptation to the cold climate of its habitat. Compare MASTODON.

From the earliest times fossil ivory was derived from the buried tusks of these elephants. The ancient Chinese worked in it, and even had such ideas about the edibility of the animal's flesh as make it probable that they knew that carcasses were occasionally found on the Arctic coast. This ivory was known to the Greeks, and the "licorne" sent as a present by Harun al Rashid to Charlemagne is believed to have been a mammoth's tusk. Arabic writers of the tenth century mention it as an article of regular Russian trade, and ever since that time fossil ivory has come from Siberia at a rate calculated to be not less than 100 pairs of tusks a year.

Among the strange conceptions of the animal which furnished this ivory that arose among people unfamiliar with elephants was that of the Chinese, who said it must be a mole, because its remains were always found underground. This was not so illogical as the pious hypothesis in Europe that the bones were those of St. Christopher. The gathering of this antediluvian heritage continues to be a regular business along the Arctic coast. In 1799 one of the ivory hunters discovered in the cliffs of perpetually frozen earth and ice which border the course of the lower Lena River a shapeless mass which three years later, under the influence of a succession of unusually warm summers, had been released from its tomb and fallen to the foot of the cliff. In March of 1803 the hunter visited it and cut off and carried away the tusks, which he sold for 50 rubles. In 1806 the animal was examined by a scientific man. The Yakuts of the neighborhood had cut off the flesh to feed their dogs, and the wild beasts had almost entirely cleaned the bones. The skeleton was, however, nearly entire, and some of the bones were still held together by ligaments. The head was covered with dry skin, and one of the ears, which was well preserved, was furnished with a tuft of hairs. Three-fourths of the whole skin was procured; it was of a dark-gray color, and was covered with a reddish wool, and long black hairs or bristles, forming a long mane on the neck. The entire carcass, together with the recovered tusks, was removed to St. Petersburg, where it is now preserved. Since that period several other carcasses have been disentombed by melting or floods, but, in spite of strenuous efforts, no valuable parts have been recoverable.

What caused the disappearance of the mammoths has not been satisfactorily explained. To judge by the extraordinary abundance of the remains, this elephant must have been excessively numerous throughout most of its range. It seems fitted to withstand any cold to which there is reason to suppose the species was ever exposed, at any rate in the southerly parts of its range. At its period the present treeless areas of northern Asia were covered with forests of pine, upon whose leaves and underbrush the elephants were accustomed to feed. The disappearance of these forests would account for the extinction of this and associated extinct animals in that region, but the question as to the rest of the habitat remains unanswered. There is no doubt that in western Europe, and probably in America, mammoths survived not only the advent of mankind but even his advancement to the neolithic stage. Of this a variety of evidence exists, including unmistakable and really excellent etchings made by the "cave men" of southern France, some upon pieces of the animal's tusk. That those men, assailing the mammoth in numbers, driving it into inclosures and entrapping it in pitfalls, could overcome it cannot be doubted; and it is probable that in Europe the waning species was terminated by man.

The relationship of the mammoth to other fossil elephants, and its place in the evolutionary history of its family, will be found treated in the article ELEPHANT, *Fossil Elephant*.

Consult the authorities mentioned under ELEPHANT; also F. E. Beddard, "Mammalia," in *Cambridge Natural History*, vol. x (New York, 1902); F. A. Lucas, *Animals of the Past* (ib., 1901); W. B. Scott, *History of Land Mammals in the Western Hemisphere* (ib., 1913); O. F. Herz, *Frozen Mammoth of Siberia* (Washington, 1904).

MAMMOTH CAVE. The largest known cavern in the United States, situated in Edmonson Co., Ky., near Green River, 125 miles southwest of Lexington (Map: Kentucky, D 5). The Mammoth Cave—discovered in 1809 by a hunter named Hutchins—consists of a series of caverns that have been explored for many miles. Its mouth is about 600 feet above sea level. Several streams occur in the cave, the principal one being the Echo River, which has a length of nearly ¾ of a mile and communicates through an underground passage with Green River. The Styx, about 450 feet long, is remarkable for a natural bridge of great beauty. Passages and avenues connect chambers or halls situated at different levels, thus showing the slow progress of the underground stream in its course through the earth. The largest chamber—named the Chief City—is 450 feet long and 130 feet wide. Several other large chambers or domes extend through the entire height of the levels. The most notable of these domes are the Stella, Mammoth, and Gorin's, each about 250 feet high, and Lucy's Dome, over 300 feet high and 60 feet in diameter. Cleveland Avenue extends for more than 2 miles and presents a most wonderful variety of crystals and incrustations. All of the halls offer to view numbers of stalagmites and stalactites, whose varied and contrasting shapes or grotesque resemblances to natural or architectural objects, in conjunction with the streams, lakes, cataracts, and fountains, form the wonderfully picturesque scenery of the cavern. Startling effects are produced by the use of lights and fireworks, the Star Chamber showing on its ceiling myriads of glistening points, from which it takes its name.

The Mammoth Cave is but one of an extensive system of caves occurring over an area of not less than 8000 square miles in Kentucky and Tennessee. The process of formation seems to have been as follows: Rain water and melted snow more or less charged with carbonic acid gas, and having the power of dissolving limestone, makes its way downward by means of joints and bedding planes in the rocks, and finally comes to the surface again as springs at levels determined by the larger drainage systems of the country. From the surface downward this flowing water dissolves out sink holes and pipes; in its horizontal progress towards an outlet it carves out the caverns. The gradual lowering of the beds of larger river systems permits lower outlets for these subterranean waters, thus leaving the older galleries dry. The atmosphere of Mammoth Cave varies little from 54° F. the year around. The animal life of the cave consists of a few species of fish and crayfish and several species of insects and bats. Consult H. C. Hovey, *Celebrated American Caverns* (Cincinnati, 1882); id., *Mammoth Cave of Kentucky* (Louisville, 1912). See CAVE ANIMALS.

MAMMOTH HOT SPRINGS. A group of thermal springs in the extreme north of the Yellowstone National Park in northwestern Wyoming (Map: Wyoming, A 1). The waters deposit calcium carbonate in the form of travertine, which covers an extent of over 1000 acres. The deposition of this material has built up a series of basins, some of which have a diameter of nearly 100 feet. The hottest spring is 165° F. These springs have no rival in the world since the terraces of Rotomahana in New Zealand were destroyed by a volcanic eruption.

MAMO, mä′mȯ (Hawaiian name). A peculiar creeper-like bird of the Sandwich Islands (*Drepanis pacifica*), the only representative of the family Drepanidæ and now extinct. Its destruction was brought about early in the nineteenth century, "for the sake of its rich yellow feathers used in former days to decorate the state robes of the chiefs." Very few skins are in existence, and these are preserved in European museums. After the extinction of this bird resort was had to another, the oö or moho (q.v.), to supply yellow feathers, while red feathers for the purpose were obtained from the scarlet creeper (*Vestiaria coccinea*). Consult Wilson and Evans, *Birds of the Sandwich Islands* (London, 1884), and W. Rothschild, *Extinct Birds* (ib., 1907). See MOHO.

MAMORÉ, mä′mȯ-rā′. A river of Bolivia and the principal head stream of the Madeira, being by many geographers considered as the upper course of that river (Map: Bolivia, D 6). It rises on the east slope of the Cordillera Real, not far from Oruro, and flows first southeastward under the name of Río Grande, then north, northwest, and again northward, receiving from the right its main tributary, the Guaporé, after which it forms the boundary between Brazil and Bolivia until it unites with the Beni to form the Madeira. After leaving the mountains it flows partly through extensive grazing plains, partly through immense forests. Its course is throughout so swift that even in the forest region it is continually shifting its bed. The length of the Mamoré is over 1300 miles, and it is navigable for nearly 1000 miles. Most of its tributaries are also navigable after they leave the mountains and enter the great plains. The river is, however, obstructed by falls and rapids, especially those of Guajara, 40 miles above the junction with the Beni, and by dams of fallen logs, so that it is navigable practically over a continuous stretch of only about 400 miles above the Falls of Guajara.

MAM′PALON, or **MAMPELON** (from the native name). A semiaquatic civet-like animal (*Cynogale bennetti*) of the Malayan region, which feeds upon fish, crustaceans, and the like and has many curiously otter-like ways and adaptations. It is a member of the family Viverridæ, related to the hemigales and paradoxures.

MAMUN, mȧ-mo͞on′. A distinguished caliph of the Abbaside line, son of Harun al Rashid. See Al Mamun.

MAN. A food used by Arabs. See Coccidæ.

MAN, Antiquity of. See Man, Science of.

MAN, Henry (1747–99). A friend of Charles Lamb. He was born in London and educated at the Croydon Grammar School, then under Rev. John Lamb. At the age of 15 he became clerk in a London mercantile house. In 1776 he was appointed deputy in the South Sea House, where he formed a friendship with Lamb. He is "the wit, the polished man of letters," sketched by Elia. Man's publications comprise mainly the *Trifler* (1770), essays; letters on education contributed to the *Morning Chronicle* (1774); *Cloacine* (1775), a dramatic satire. Consult *Collected Works*, with memoir (London, 1802).

MAN, Isle of. An island in the centre of the Irish Sea, whence its Manx name *Vannin* or *Mannin*—the middle—16 miles south of Burrow Head and 27 miles equidistant from England and Ireland (Map: England, B 2). It is 32 miles long, 12 miles broad, and 227 square miles in area. At the southwest extremity is an islet called the Calf of Man, containing 800 acres, largely cultivated. The scenery is varied and picturesque. A mountain chain extends from northeast to southwest, culminating in Snaefell, 2034 feet above the sea; from its summit the view embraces the wooded glens and undulating country in the foreground; the rich plains of the north and south of the island in mid-distance; and beyond, the Irish Sea, bounded by the highlands of the surrounding countries. Several trout streams take their rise in these mountains.

The island is situated on the eastern platform of the Irish Sea and belongs physically more to England than to Ireland. It is composed mainly of Silurian rocks and Carboniferous limestones, through which granite bosses have extruded. In these features it is similar to the Lake District of England, of which it is an outlier. Great quantities of lead are extracted annually, as well as considerable quantities of copper, zinc, and iron; the lead ore is the richest in silver in the United Kingdom. The climate is remarkable for the limited range of temperature, both annual and diurnal; westerly and southwesterly winds predominate, easterly and northeasterly winds occurring chiefly in the autumn quarter. Myrtles, fuchsias, and other exotics flourish throughout the year. Agriculture is followed, especially in the southern part of the island and in the level districts to the north. On the hillsides in the interior many cattle and sheep are pastured. The island is noted for a breed of tailless cats. The Isle of Man is a great summer resort for operatives of Lancashire and Yorkshire, and at various points dancing pavilions have been erected. Steamers ply regularly between it and Liverpool, Fleetwood, Barrow, Silloth, and other ports. The herring, mackerel, and other fisheries are important. The manufactures are unimportant, but the natives derive a large income from the thousands of visitors that come to the island each season.

There are many interesting antiquities on the island. Near Castletown, the ancient capital of the island, is the well-known Castle Rushen, which was once the palace of the native kings. Douglas, the capital of the island and its principal seaport, contains the so-called Tower of Refuge, and the former residence of the dukes of Athol. Sixteen miles from Douglas lies Port Erin, a picturesque watering place on a small bay. Between Douglas and Peel, a distance by rail of 12 miles, is Greeba Castle, the residence of Hall Caine, whose writings have done much to make the manners and customs of the Manx familiar to the general public. Peel is remarkable for its castle on St. Patrick's Isle, joined to the mainland by a causeway, which in its present form dates chiefly from the fifteenth century. The ruins of the cathedral stand within the castle inclosure.

The Isle of Man forms a separate bishopric under the title of Sodor and Man. The Manx church has its own canons and an independent convocation. The see is, for certain purposes, attached to the Province of York. There are in the island about 40 places of worship in connection with the Established Church of Man. The livings are, with few exceptions, in the gift of the crown. The principal denominations of dissenters are represented in the island.

The Isle of Man has a constitution and government of its own, and is not bound by acts of the Imperial Parliament unless specially named in them. It has its own laws, law officers, and courts of law. Government is administered by the Court of Tynwald; this consists of the Lieutenant Governor, who is the chief executive officer, the Legislative Council, and the House of Keys. The Lieutenant Governor is appointed by the crown. Besides the Lieutenant Governor, the Council includes the Lord Bishop, the Clerk of the Rolls, the two deemsters, the Archdeacon, the Attorney-General (all of whom are appointed by the crown), and the Vicar-General (appointed by the Bishop). The Council is the upper legislative body and the House of Keys the lower. The latter, a representative assembly, consists of 24 numbers elected by male and female owners or occupiers of property. Legislative acts are valid only upon the signature of the Lieutenant Governor and the assent of the British sovereign in council. The native language, Manx, a dialect of the Celtic, is still spoken, and is taught along with English in the parish schools. It is spoken chiefly in the northwestern parishes and in certain localities on the west coast. It has a marked similarity to the Irish and Gaelic dialects. Public elementary instruction was established in 1872 and secondary instruction in 1907.

In 1912 there were 76,303 acres of arable land and 16,745 acres under permanent grass. To grain crops were planted 22,526 acres, of which 19,302 to oats; turnips and swedes, 8017 acres; potatoes, 2558; clover, sainfoin, and grasses under rotation, 41,684. Live stock (1912): 5978 horses, 21,188 cattle, 80,422 sheep, and

4329 swine. The mineral products include lead, zinc, and salt.

The history of the Isle of Man is involved in obscurity until near the end of the ninth century, when the Norwegian Harald Haarfagr conquered the Welsh kings and took possession of the island. In the beginning of the tenth century, according to the legend, Orry, a Dane, effected a landing, and was favorably received by the inhabitants, who adopted him as their king; he is said to have been the founder of the present Manx constitution. A line of Scandinavian kings succeeded until Magnus, King of Norway, ceded his right in the island and the Hebrides to Alexander III of Scotland, 1266. On the death of Alexander the Manx placed themselves under the protection of Edward I of England by a formal instrument dated 1290; on the strength of this document the King of England granted the island to various royal favorites from time to time, although their possession was contested by the Scottish kings until after the battle of Neville's Cross in 1346. In 1406 it was granted to Sir John Stanley in perpetuity, to be held for the crown of England, by rendering to the King, his heirs and successors, a cast of falcons at their coronation. With the exception of a short period during the Civil War, when the island was surrendered to a Parliamentary force by Receiver-General Christian and was granted to Thomas Lord Fairfax, it remained in the possession of the Stanley family and their descendants until, having been for a long period the seat of an extensive smuggling trade, to the detriment of the Imperial revenue, the sovereignty of it was purchased by the British government, which paid in 1765 £70,000 plus an annuity of £2000 for the customs duties and in 1828 £417,144 for the sovereignty. Pop., 1891, 55,608; 1901, 54,758; 1911, 52,016.

MAN, SCIENCE OF. Especially during the later half of the nineteenth century and the opening years of the twentieth, scientific methods were extended to the study of man in various aspects, and a series of special sciences relating to different attributes or characters of the human being grew up. Among these are physiology, craniology, psychology, archæology, sociology, demology, ethnology, and various subdivisions of these, as well as several broader sciences dealing with common attributes of mankind and lower organisms, such as morphology, embryology, ecology, etc. By some writers the several branches of knowledge dealing specifically with the human kind are treated as coördinate and more or less distinct, and by some of these anthropology is applied, as one of the series of coördinate terms, to the science of the human body or somatology. Other writers employ the term "anthropology" in a more general sense, including within its scope the special sciences dealing not merely with the human genus, but with men and their works in all their multifarious aspects; and this usage is to be preferred both on logical grounds and in the interests of convenience. Accordingly the science (or sciences) of man may be defined as equivalent to anthropology in the broad sense, i.e., as including the various branches of definite knowledge pertaining to mankind.

In a broad sense the science of man may be defined as the science of (1) the human organism, (2) the human mind, and (3) the human activities and their products; and these categories correspond respectively with the sciences of (1) somatology, (2) psychology, and (3) demology. These branches of knowledge are themselves complex. Somatology comprises human anatomy, physiology (and pathology, etiology, etc.), craniology, embryology, and ecology, in addition to anthropometry, craniometry, medicine, surgery, constructive hygiene, and other collateral branches; psychology comprises phrenology (of course in the sense of observational knowledge concerning cerebral structure and functions), neurology, etc., together with such collaterals as psychometry, both introspective and experimental psychology, and the inchoate systems of cerebral cultivation sometimes called psychurgy; while demology is more definitely organized as (*a*) esthetology, or the science of arts; (*b*) technology, or the science of industries; (*c*) sociology, or the science of laws; (*d*) philology, or the science of languages; and (*e*) sophiology, or the science of ideas—the last comprising mythology, theology (in certain aspects), philosophy, teleology, and other more or less interrelated systems of thought. There remain certain sciences dealing with special aspects of the field covered by these divisions; thus, ethnology is the special aspect of anthropology pertaining to racial characters and types, while archæology deals with the prehistoric aspects of somatology, esthetology, and technology so far as these are known through relics. So, also, several of the sciences have commonly recognized descriptive aspects, such as craniography, demography, ethnography, etc. The leading divisions and branches of the science are shown in the accompanying table:

Science of man	Somatology	Anatomy Physiology	Anthropometry
		Craniology	Craniometry
		Embryology Ecology, etc.	
	Psychology	Phrenology Neurology, etc.	Psychometry, etc.
	Demology	Esthetology Technology	Archæology
		Sociology Philology	
		Sophiology	Mythology Theology Philosophy Teleology, etc.

Manifestly the science of man as thus defined cannot be treated in detail within moderate limits. Under the title ANTHROPOLOGY the conventional limitations of that science have been defined, and likewise the special articles on the several topics enumerated above may be consulted for each in turn.

ANCIENT TYPES

Recent discoveries in the domain of human paleontology lead to two outstanding conclusions in regard to ancient types of man, for the remains now available for study include some specimens which can only be assigned to beings —or, as the zoölogist terms them, "forms"—of a nature bordering on the very confines of humanity. In the second place a paleolithic type is now known which, though undoubtedly human, differs from all other human forms (extinct or otherwise) so completely as to require the distinction of a separate species. Such a distinction is not accorded readily by anthropologists; it cannot be conferred with justice upon any other variety of mankind in any part of the globe. All existing varieties are assignable to the species *Homo sapiens*, with which one other, viz., *Homo primigenius* (*neanderthalensis*), must be contrasted.

The evidence for these conclusions and the range in time throughout which the two species of the Hominidæ can be traced will be considered in the sequel. But even at the risk of anticipating a verdict, it is well to emphasize the fact that the prehistoric period has now supplied examples of forms differing in certain essential details from modern men, and that two grades can be recognized in the differences detected in the skeletons.

The very mention of the skeleton reminds the student that, when attempts are made to reconstruct prehistoric human forms, the essential materials consist of the actual remains of individuals preserved in a fossil state. Not that these exhaust the means of inquiry or research, for even though the evidence of stone implements be ruled out, the representation of human forms is not unknown, and the latter may be revealed as paintings or even as objects of sculpture. Yet such evidence lacks the cogency provided by the bones themselves, and indeed only the bones are recoverable from those early deposits and periods in which the evolution of man may be expected.

Upon such considerations the present field of survey will be limited to evidence provided by skeletons and the circumstances in which these have been brought to light. A distinction must be drawn here between cave finds and such as have been made in gravel beds or other deposits not inclosed in a circumscribed space. Caves often yield evidence of a kind more precise than that obtainable from an alluvial stratum in the open. Caves were frequently used as habitations, occasionally and alternatively as places of sepulture, and a careful record of the succession of layers or strata in the floor of a cave usually leads to a fairly precise determination of the relative antiquity of any interment that may be encountered. Lastly, skeletons from caves are often perhaps usually much more complete than those found in the alternative conditions of an alluvial deposit.

Such deposits, though encouraging expectation in the highest degree, frequently prove disappointing, and this indeed depends on their very nature. If the reason for this result be sought, it will be found in the fact that in such researches the true value of the bones can be realized only if they are of the same antiquity as the deposit. The torrential floods or boisterous tides which threw the débris up in banks do not tend to good preservation of skeletons. Exceptions fortunately occur where a corpse has been swept into a backwater, there to be silted over and thus preserved.

Such are some of the reasons for contrasting caves with alluvial strata as sources of the bones which may testify to the former existence of mankind. It will be understood that the discovery of a fairly complete skeleton in a gravel bed is in the majority of instances suggestive of an interment subsequent to, perhaps later by many millennia than, the deposition of the material in which the bones were found. Such examples require the support of very complete evidence before contemporaneity can be regarded as proved.

The statement just made in regard to the expectations aroused by the alluvial deposits and their contrast in this respect with cave specimens must now be explained. Alluvial deposits often yield remains of animals, and the study of these remains has assisted enormously the work of classifying the deposits. Some of them are now known to possess a very great antiquity within the limits of that part of the geological time-table with which we are concerned. Announcements appear from time to time testifying to the discovery of human artifacts such as stone implements in even the more ancient of these deposits. Such discoveries (of implements) produce an effect even when no human remains are discovered in the same place or on the corresponding horizon. One result is to stimulate the search for the makers of the implements in the places or horizons concerned. Of late years announcements of the discovery of implements made by man in times of the remotest antiquity have been numerous and more confident than ever before. Without prejudice indeed they may be termed sensational, and in consequence estimates of the duration of human existence are correspondingly affected.

Cave deposits rarely if ever carry us back to those remoter epochs represented by the more ancient alluvial deposits, which are thus shown to be capable of extending the evidence of man's presence backward to an incomparably greater degree. But the anthropologist who desires above all to avoid errors must of necessity scrutinize with every care the evidence for the antiquity of the deposit, as well as that submitted in support of the artifacts. The claims made for the implements, to the effect that they are artificial and not the result of some natural process, must not be overlooked, and all such inquiries pave the way to a further investigation, which arises only when human bones are found in the like suspicious surroundings.

The foregoing remarks will serve as an introduction to the scheme or chronological arrangement of the more important remains of prehistoric man. The tabulation presented on page 750 will serve conveniently the purpose of a more detailed account of the relations of the various specimens. Marks of distinction show the origin of each, i.e., whether from an alluvial deposit or from a cave. In the earliest series the two examples described as authenticated must be regarded as referable with certainty to the horizons of the very early (i.e., ancient) deposits in which they lay. The claims to a corresponding antiquity made on behalf of some other specimens have been combated with more success, and the latter are for this reason separated under the head of doubtful examples. The Trinil and Mauer bones present such extraordinary characters that they can claim an interest of unparalleled kind, but unfortunately the skeletons are represented by small portions only. Both were found in river alluvia, and the lower jaw is the sole portion of the Mauer skeleton so far discovered. The bones bear witness to the former existence of beings to which the very term "human" must be employed with reservation. More particularly is this the case in regard to the Trinil remains. Some of the more important characters of these may now be reviewed. The outstanding feature is that the bones indicate an individual similar in stature (and presumably in weight) to a well-developed modern man. Yet the brain case is extraordinarily deficient in capacity if judged by a human standard, for herein it falls much below the lower limit of variability in modern skulls. The brain case is particularly defective in its vertical diameter (or "height") and in its longitudinal curvature. These defects combined with the lack of width at the temples and the prominence of massive brow ridges provide the strongest possible suggestion of the manner in which the human type was derived from that of an ape.

SERIES	AUTHENTICATED		DOUBTFUL

Magdalenian	Combe Capelle (France) † Chancelade (France) †		

* From an alluvial deposit.
† Cave deposit.

In spite of this conclusion the Trinil calvaria, or skullcap, presents certain characters which, taken together with those of the thigh bone, constrain the anatomist to range the *Pithecanthropus erectus* on the human side of the zone or space intervening between the forms of man and apes. The Mauer jaw provides material for similar conclusions, for whereas its enormous mass alone suggests the ape, its dentition and some details in the region of the chin proclaim that an advance has been made in the direction of the distinctive human conformation. While it is debatable whether or no the Mauer jawbone is appropriate to such a skull as that from Trinil, it seems probable that the Mauer fossil represents a slight advance in evolution from the stage exemplified by the skeleton from Java.

For the moment it is convenient to defer consideration of the series of doubtful specimens. It must not be supposed that these are to be placed unreservedly out of court, although for the moment they are passed by. Proceeding to the next series of well-authenticated finds, we encounter a group referred to the Middle Paleolithic period of the well-known classification employed by archæologists.

The skeletal remains of Middle Paleolithic antiquity constitute a fairly homogeneous assembly. This may be designated provisionally the type of *Homo primigenius.* The descriptive term is due to Professor Schwalbe, of Strassburg, who has added so much to a proper appreciation of the nature and relations of these fossil forms. The alternative designation of *Homo neanderthalensis* is also employed, chiefly by Professor Boule and his colleagues in France. But although the arguments employed by the latter against the adoption of the term *Homo primigenius* are of no small weight, nevertheless that expression will be employed in the following paragraphs as providing a more generally applicable name for the type in question.

Fragmentary skeletons representing nearly a score of individuals have enabled anatomists to reconstruct with confidence the salient features of this type. The materials come from localities distributed widely over the surface of Europe, viz., from Croatia to the Channel Islands and from the Neanderthal (near Düsseldorf) in north Germany to Gibraltar. The characters presented by the skeleton of *Homo primigenius* may be summarized by the statement that this form is quite definitely and distinctively human, but that nevertheless it occupies a position inferior to all the existing Hominidæ and to all prehistoric representatives of mankind, the Trinil and Mauer fossils alone being excepted, for *Homo primigenius* is superior only to *Pithecanthropus* and to *Homo heidelbergensis.*

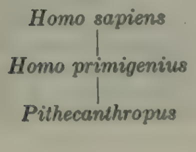
The foregoing statement is justifiable, even though we concede the large amount of brain claimed for at least several examples of this otherwise lowly type. The size of the brain is naturally a matter of inference, but the size of the skull gives reliable information on this point, and it must not be forgotten that *Homo primigenius* seems to have been in some instances even better provided with brain material (if the mere weight be taken as a test) than the average *Homo sapiens* of to-day.

Yet the form of the brain is not to be overlooked, and examination of the brain case shows clearly enough that the lack of vertical height and of curvature in the longitudinal arch of the skull are very characteristic of *Homo primigenius.* These defects or shortcomings are expressive of corresponding features in the brain; they are also reminiscent of the conditions noted above as distinctive of the brain case of *Pithecanthropus* (Trinil). The term "reminiscent" is employed advisedly, for in *Homo primigenius* a distinct advance is observed as having been made from the earlier stage. In a similar way, when the Mauer jaw is brought into comparison, distinct advances on the part of *Homo primigenius* may likewise be detected.

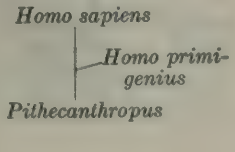
Passing from the skull to other parts of the skeleton, we must note that the distinctions between *Homo primigenius* and *Homo sapiens* are evident in almost every bone so far subjected to examination. Here it will suffice to note that all the indications are in favor of assigning a low stature to *Homo primigenius,* and while this does not serve to distinguish him absolutely from *Homo sapiens,* it would apparently differentiate him from *Pithecanthropus erectus* (with 5 feet, 8 inches of height). Returning to the tabulation given, we pass to the Upper Paleolithic series. In this group the skeletons no longer present the characters of *Homo primigenius,* and it is noteworthy that the latter disappears completely at the end of the Middle Paleolithic period. In most of the instances that follow, no fundamental distinction from European man is to be detected. In exceptional cases, however, the skeletons are said to present somewhat remarkable characters. Thus, two skeletons from Mentone referred to the Aurignacian period are said to possess features allying them to the negro types of Africa. Another skeleton of Aurignacian antiquity (viz., that from Combe-Capelle) has been compared in some details to certain Oceanic (Melanesian) negro types, and the so-called Chancelade skeleton is alleged to resemble the Eskimo type in regard to the proportions of the brain case and the form of the facial bones.

Such suggestions conjure up possibilities of a far-reaching significance in regard to the evolution of racial types and the dispersion of the fully evolved products; but while recognizing these possibilities, we should bear in mind the extraordinarily feeble basis upon which the suggestions are made. Two crania from Mentone (Grotte des Enfants), one from Combe-Capelle, and one from Chancelade are employed to represent three well-marked existing types. The identifications are made on a few points only, not upon a continuous and unmistakable succession of coincidences in conformation, so that until many more crania are available and many more points of identity shall have been demonstrated, these matters are for surmise and suggestion only. With the Upper Paleolithic series this part of the present survey comes to an end. It appears that, on the whole, the evidence of the skeletons described above points to an evolution from forms corresponding to the Trinil and Mauer types onward to that of *Homo primigenius* and thence to that of modern man. It would be misleading to leave the reader to suppose that we have here a direct line of descent and that *Homo heidelbergensis* was directly ancestral to *Homo primigenius,* as the latter was to *Homo sapiens.* Upon such evidence as is available there is good reason to suppose that *Homo primigenius* had diverged in no small degree from an analogous form destined in course of time to provide by evolution the more highly developed *Homo sapiens.* Two alternative points of view of this subject are contrasted by Professor Schwalbe, who illustrates them by means of such schemes as those following (labeled *A* and *B* respectively):

A

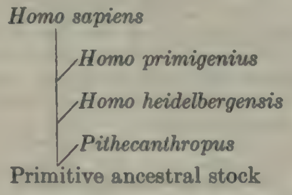


B



Of these schemes, *A* represents what may be termed that of direct ancestry, *B* the mode described above as an alternative; and we may note that Professor Schwalbe himself pronounces in favor of *B.* But yet another possibility exists, for we must not postulate that the form of *Pithecanthropus* discovered at Trinil is that of a direct ancestor. This view may be illustrated also in schematic fashion as in diagram *C.*

C



Thus, *Pithecanthropus, Homo heidelbergensis,* and *Homo primigenius* in turn aid us to realize the appearance of successive ancestral stages, but we may yet identify them with actual ancestors. The distinction may appear too finely drawn, but in such a matter it is of some importance.

Allowance being made for such necessary correction of evidence, these fossil remnants enable us to retrace the course of human evolution to a stage not far removed from that of the anthropoid apes; and in point of time this process appears to extend backward as far as this end of the Pliocene division of the Tertiary period. The course of that evolution agrees in a remarkable manner with that anticipated by evolutionists and in particular by Huxley. We may note that the change in the absolute size or mass of the body is not great, and thus the suggestion has gained ground to the effect that the Hominidæ are derived from what are known as "giant forms" among their congeners the Primates.

The bones of the limbs and trunk do not as yet provide such definite information as might have been expected; for though these parts in the ancient skeletons possess many characters suggestive of a lowly origin, yet the bones are quite definitely those of mankind and not those of apes. Thus, the thigh bone of *Pithecanthropus erectus* is far more human than the skullcap of that form. Again, when the limb bones of *Homo primigenius* are called in question, the conformation of the foot (though not without peculiarities) does not provide evidence that the foot was really prehensile. The power of prehension still exists in a small degree, but it does not appear that *Homo primigenius* greatly excelled some of the existing human types in that respect. For the rest, there are certain features of the ribs and some bones of the hand which indicate that *Homo primigenius* had progressed along a line of development upon which the real ancestors of *Homo sapiens* may have never entered. Nevertheless, distinctive features have thereby been imprinted upon the skeleton of *Homo primigenius,* and they are probably not relevant at all in regard to the evolution of mankind in general.

Thus we are led to consider the skull and the general trend of the evidence provided by this part of the skeleton. First, the diminution in size of the jaws and teeth may be mentioned. Concurrently with this diminution an increase in the capacity of the brain case is remarked, but in regard to the last-mentioned feature a very curious irregularity of increase has been recorded. Thus, the skull of *Pithecanthropus* was undoubtedly of small capacity (of the skull of *Homo heidelbergensis* nothing apart from the lower jaw is known). The irregularity mentioned above appears when the various examples of *Homo primigenius* are considered. Among these the examples from Forbes Quarry (Gibraltar) and La Quina (France) have brain cases of very small capacity when judged by the standard of *Homo sapiens*, though markedly in excess of the figure quoted for *Pithecanthropus;* but other examples of *Homo primigenius* surpass in point of skull capacity (and consequently of brain mass) most of the more highly developed modern types of *Homo sapiens*. Indeed, if the crania from the Neanderthal, La Chapelle-aux-Saints, and Le Moustier be employed to provide an average value for skull capacity in cubic centimeters, there are few modern races of Hominidæ capable of furnishing a higher figure. Yet the skull enables the anatomist to obtain some little information as to the form of the brain as well as its size and probable weight; and by making a cast of the interior of the skull, the dimensions and proportions of the brain can be determined. Such researches have been made recently by Professors Boule and Anthony at Paris. They examined brain casts of the small-brained skull from La Quina and also of the megacephalic cranium from La Chapelle-aux-Saints. In both a like evidence of a lower status was found in regard to the actual form of the brain as distinguished from its size. One of the most distinctive features is the relatively flattened form of the brain as a whole. In other words, the vertical diameter is small, and the longitudinal arc is much less boldly curved than in the modern type of brain. The same feature has been noted already in reference to the cranial curvature and vertical dimensions, and the skulls and brain casts alike indicate that the brain developed in length and breadth before attaining its present stage in point of height.

Whether the human brain can claim priority in evolution over the changes in the skeleton, rendering possible the erect attitude, is a problem not yet solved—at least there is not yet a general agreement on this point; but on the whole the considerations urged in favor of an increase in the brain as the primary step appear to outweigh the objections to that view. Such a summary of the present position in regard to the mode of human evolution might suffice were the specimens ranged under the heading "authenticated" in the tabulation all that the anthropologist had at his disposal. Such is not the case, and reference to the doubtful instances is necessary since, should they be authenticated, very distinct qualifications would be necessitated in the account of man's origin as set forth above. The specimens now to be considered are divisible into two groups, or rather the Piltdown fragments stand in strong contrast to all the rest. The latter do not differ essentially from modern human skeletons, but they are not wholly deprived of interest on that account, for to some of them an antiquity equal to that of the Mauer or Trinil bones has been assigned. If the type of *Homo sapiens* can really claim such antiquity, the ancestral forms must be sought in earlier periods and strata than any mentioned hitherto in this article. *Pithecanthropus*, *Homo heidelbergensis*, and *Homo primigenius* would still be regarded as reminiscent of some of those ancestral stages, but they would then appear as remnants persistent long after their particular stage had been passed through by *Homo sapiens.* We may remark at once that in the earlier strata thus brought into consideration, nothing so suggestive of the immediate evolution of man has yet been found to compare with the Trinil and Mauer fossils.

The periods antecedent to the Pliocene divisions of Tertiary time are termed Miocene, Oligocene, and Eocene respectively, the Eocene being the oldest. If the fully evolved *Homo sapiens* existed in the Pliocene epoch, then the ancestral stages corresponding to *Homo primigenius* and the like might be expected in the Miocene epoch or even earlier. It is then at least conceivable that eventually the existence of Eocene man may be demonstrated by the discovery of unequivocal evidence of his presence in Eocene deposits. Archæologists who follow Professor Rutot, of Brussels, claim acceptance of the proposition, on the ground that human artifacts have been discovered in Eocene and under circumstances testifying to the similarity in age of the implements and their immediate surroundings. This is, however, the extreme case, and though implements of such vast antiquity are said to be forthcoming, no human bones have yet been assigned to any deposits earlier than the latest of the Pliocene series.

Under the circumstances it is possible to adopt only a noncommittal attitude and to express the view that possibilities and not certainties are thus indicated. Moreover, as the specimens do not differ in any important details from the bones of modern men, they provide no anatomical evidence on the problem of human evolution.

We turn now to the one remaining instance, viz., the fragments of a skull from Piltdown in Sussex, England. They consist of portions of a skull of which a part came some years ago into the hands of Mr. Dawson, of Lewes. The skull has been reconstructed, and from its peculiarities it has received the distinctive name *Eoanthropus*.

Eoanthropus dawsoni is thus represented by parts of a skull only. No parts of the limbs are known, so that the information provided by them in regard to stature and bulk is lacking. The skull fragments were recovered from an ancient gravel deposit. They are completely mineralized. Estimates of their antiquity are divided between the later Pliocene epoch and the early Paleolithic division of Post-Pliocene time. It is perhaps significant that these alternative estimated are ranged, one earlier than and the other later than that given for the Trinil and Mauer fossils. In either case they are assigned to an earlier period than that of *Homo primigenius.*

But the fragments possess an overwhelming interest quite apart from their antiquity. This interest is concentrated about two points. The first of these is that, according to Professors Elliot Smith and Smith Woodward, *Eoanthropus* had a small brain and in the conformation of the brain agreed with the Gibraltar (Forbes Quarry) and La Quina representatives of *Homo primigenius.* The thickness of the skull is another feature of agreement, but the skull of *Eoanthropus* even surpasses that of *Homo primigenius* in this respect. Yet the brow region of the skull is in *Eoanthropus* more suggestive of the modern-type man of *Homo primigenius*, and the temporal bone is also in important respects similar to those of modern skulls.

The second point is that the lower jaw makes a closer approach to the form characteristic of apes than does any other specimen, even that of *Homo heidelbergensis.* The Mauer jaw is accordingly displaced from the position of distinction, if not of eminence, formerly occupied by it.

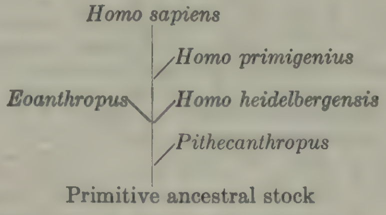
Not only is the lower jaw of *Eoanthropus* remarkably pithecoid in form, but a canine tooth of quite extraordinary size and length was found in the same gravel bed. Though found at a later date, this tooth is said to be appropriate to the jaw, and it enhances the ape-like character of the latter. Yet the lower jaw is so inappropriate to the temporal bone of the skull with which it articulates that, but for the proximity of the two as regards the locality of discovery, it is probable that the jaw and skull fragments would not be referred to the same type, much less to one and the same individual. So extraordinary a combination of characters is met with in no other instance, and it is for future discoveries to confirm or modify the correctness of the association of these fragments as parts of a single skeleton.

The combination has been questioned by some authorities of repute. As regards the brain case itself, the first reconstruction prepared by Dr. Smith Woodward has been modified, with consequent alteration of the volume of the brain. (It is impossible to state whether the volume has been increased or decreased, for diametrically opposed opinions are held on this point. On the whole it is probable that a slight increase has been effected.) Even so, the reconstructed skull is to be strongly contrasted with the reconstructions prepared by other observers. Some of the latter assign not a small, but a very considerable, cranial capacity to *Eoanthropus*, and in particular they provide it with a well-arched brain case contrasted with the flattened form given it by Dr. Smith Woodward. Although the matter is still under discussion, the balance of evidence for the moment inclines to the side of Dr. Smith Woodward. *Eoanthropus* is thus regarded as possessing a small brain case, inclosing a brain differing in some essential features from that typical of *Homo primigenius.* The size of the brain is a point of similarity (as remarked above). The facial skeleton of *Eoanthropus* must have been markedly prognathous, while the large canine teeth contributed largely to a quite peculiar physiognomy; but on the whole the stage of evolution is inferior to that of *Homo primigenius.*

If we inquire into the bearing of *Eoanthropus* on the evolution of man, we find that the brain and the brain case made an earlier advance than the face, and more particularly the lower jaw. The differences between the lower jaw in *Eoanthropus* and *Homo heidelbergensis* (Mauer) suggest that these examples represent alternative and perhaps parallel lines of evolution. The scheme of genealogical descent must therefore be modified accordingly, and diagram *C* of a preceding page may now be replaced by another, *D* (see diagram *D*).

The exact point of divergence of *Eoanthropus* is a matter of speculation, for if the lower jaw is more lowly than that of *Homo heidelbergensis*, the brain cast of *Eoanthropus* shows one character at least of high developmental significance. That character is the lack of symmetry between the right and left halves of the brain. In the apes the two halves of the brain are as nearly symmetrical as possible. In *Homo sapiens* there is a marked difference, hitherto regarded as essentially distinctive of the highest types of brain (the brain case follows the brain in this detail). Right-handedness and the concentration of the mechanism of speech on one side of the brain are said to be related to this asymmetry. But in *Eoanthropus* the difference is as marked as in any modern example, and this consequently lifts *Eoanthropus* high in the scale of evolution. Consequently, even if the point of departure be placed below that of *Homo heidelbergensis* (as in diagram *D*), the line culminating in *Eoanthropus* must be made to ascend steeply and to terminate just below the level of *Homo primigenius.*

D



Lastly, the probable antiquity of the Piltdown fragments must be recalled in this connection. The lowest estimate of that antiquity approximates *Eoanthropus* to *Homo heidelbergensis.* The higher estimates make *Eoanthropus* rather older than the Mauer fossil. (But it is noteworthy that the advocates of that higher estimate claimed that *Eoanthropus* was not very different from modern men and that the Piltdown fragments do, in fact, demonstrate the existence of Pliocene man in a stage of evolution not very different from that of *Homo sapiens.*) However this may be, the presence of *Eoanthropus* does not essentially modify the account of human evolution suggested in an earlier paragraph, though difficulties are encountered in regard to details. The Trinil form (*Pithecanthropus*) would show that in the later Pliocene epoch the ancestral stages can scarcely be regarded as human, and they suggest that earlier Pliocene ancestors would, if forthcoming, be ranked as highly developed apes rather than the lowliest of human beings. In fact, at a certain stage the discrimination becomes as difficult as that of various shades in the spectrum of white light.

Such a view of the origin of man is better founded than the alternative of referring these events to a much earlier part of Pliocene time or even to the Miocene epoch. Yet the alternative must not be overlooked in view of the very different interpretation placed by some authorities on the Piltdown fragments and other specimens included in the list of doubtful cases, and even those who accept the account given here must surely find some difficulty in reconciling complacently the lower jaw with the skull fragments of *Eoanthropus.* Future discoveries may provide the solution of the difficulty. They may prove that *Homo sapiens* existed in the *Pliocene* epoch; they may necessitate a wholesale revision of the foregoing account and show that *Homo sapiens* arose suddenly as a mutation from some quite lowly form, a form, that is to say, less highly evolved than *Pithecanthropus*. The latter, together with *Homo heidelbergensis* and *Homo primigenius*, would then appear as specialized offshoots from the stock of *Homo sapiens*, modified so far as to demand distinction of a specific order.

But if we deal with the actual materials at hand, we must adopt the view of evolution set forth above. In regard to the stages of human evolution antecedent to that represented by *Pithecanthropus*, some advances in knowledge have been made recently, but much remains to be done. Of the relevant discoveries, those made in India and in Egypt deserve special mention. The officers of the Geological Survey of India have added several fossil forms to the stock of extinct anthropoid apes, but these are mostly of the type of the larger existing varieties, such as gorilla, chimpanzee, and orang-utan. While the new fossils contribute to a general knowledge of those apes, they do not provide any definite information regarding the ancestry of those animals and of man. In point of time they are of Pliocene antiquity.

The discovery of a fossil anthropoid ape in Eocene deposits in Egypt (Fayum) is much more significant. Although the form in question is referable to the *Hylobates* group, the lowliest of the anthropoid apes, it is important as showing the rapidity of evolution of those animals. Thus, although the evidence does not admit of the drawing up of a definite pedigree, the specimens testify to the probability that in human evolution the stage of *Pithecanthropus* was preceded by a chimpanzee stage probably of Miocene antiquity, and this by a stage corresponding to the gibbon, or *Hylobates,* to which Eocene antiquity must be assigned. But the Eocene epoch provides still lower forms down to the very rootstock of the apes and other mammals. This consideration leads to the inference that at that early epoch evolution was proceeding with great rapidity; and this conclusion is justifiable, even though the vast duration of Eocene time be admitted. All recent discoveries and investigations confirm the conclusion that the great distinctive character of man—viz., the brain—has provided the determining factor throughout the course of progress from the earliest mammalian stage onward.

BRIEF NOTES ON SOME OF THE MORE NOTEWORTHY EXAMPLES INCLUDED IN THE TABULATED STATEMENT

1. *Trinil (Java)*.—The discoveries were made by Professor Dubois in the years 1891 and 1892. They consist of the upper part of the skull, a small fragment of a lower jaw, three teeth, and a left thigh bone. Professor Dubois believes that all the fragments are to be referred to one skeleton. The latter is ascribed to a form intermediate between the highest apes and man. The thigh bone is taken to indicate that the erect attitude had been attained. The name *Pithecanthropus erectus* was devised by Professor Dubois and has been accepted even by those who reject the claims to an intermediate position in evolution made on behalf of this example.

Objections to the conclusions of Professor Dubois have been based upon various considerations. The distance (about 46 feet) between the thigh bone and the skullcap (as they lay in the alluvial river deposit which yielded them) has been considered too great to allow of the association of the two fragments. The latter have been referred by some authors to a very highly developed ape, by others to an exceedingly low human type. The age of the strata in which they were discovered is also in dispute. Professor Dubois regarded this as of Pliocene antiquity, but strong claims are made for assigning it to the following Pleistocene period. No implements were found by Dubois. The nature of these fossils is therefore not entirely beyond dispute, and they illustrate clearly the difficulties encountered in dealing with fossils discovered in alluvial deposits. Consult Eugène Dubois, *Pithecanthropus erectus, Eine menschenähnliche Uebergangsform aus Java* (Batavia, 1894), translated in *Smithsonian Institution, Annual Report, 1898* (Washington, 1899).

2. *Mauer (near Heidelberg, Germany)*.—A single lower jaw, discovered in 1908. The discovery was made by a workman employed by the late Dr. Schoetensack. The jaw lay in a sandy deposit, beneath about 70 feet of superincumbent strata. The latter included both the older and newer loess deposits of the Rhine alluvial, and their presence aids in the solution of the problem of dating the jaw. This is referable to the very earliest Pleistocene period. It is extremely massive, and though in this respect it recalls the form of the jaw in a gorilla or a large orang-utan, it is clearly not to be identified with either of these forms. The chin is retreating, but characteristic human depressions are found beneath it. The teeth are relatively much smaller than one would expect in a lower jaw of such large size. On the whole, the human characters are predominant, so that Dr. Schoetensack named the form thus represented *Homo heidelbergensis*. No other part of the skeleton was found. The succession of the strata as described above, and the characters of other fossil animals found on the same horizon as the

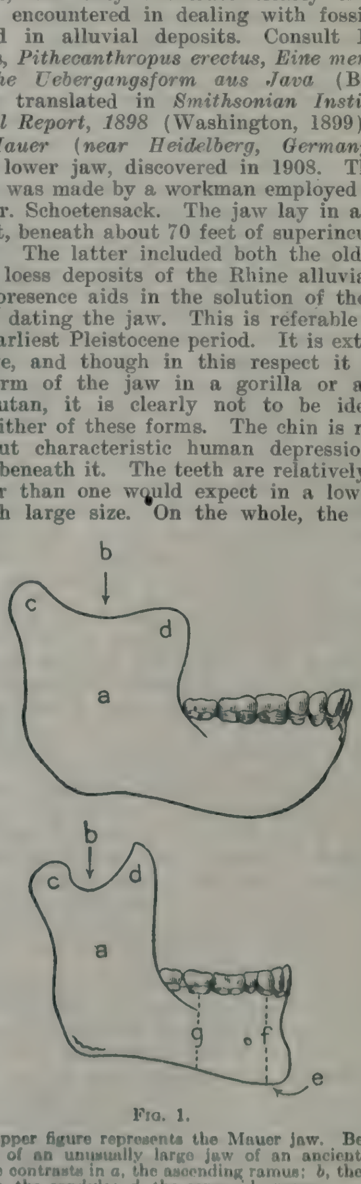


FIG. 1.

The upper figure represents the Mauer jaw. Below is a drawing of an unusually large jaw of an ancient Briton. Note the contrasts in *a*, the ascending ramus; *b*, the sigmoid notch; *c*, the condyle; *d*, the coronoid process.

Mauer jaw, form the basis for the conclusion as to its antiquity. No implements or other artifacts were found. Consult Otto Schoetensack, *Der Unterkiefer des Homo heidelbergensis* (Leipzig, 1908).

3. *Piltdown* (*Sussex, England*).—In this locality several fragments of bones were recovered from a gravel deposit by Dr. Smith Woodward and Mr. Dawson. The discoveries extend over a period of several years, but the fragments seem to have been concentrated within a comparatively limited area. They comprise a number of pieces of a skull, and these have been associated by the above-mentioned authors, who designated the form discovered by them *Eoanthropus dawsoni.* The skullcap is represented by three pieces of very great thickness. Part of the lower jaw, a canine tooth, part of a nasal bone and of one of the bones from the nasal cavity complete the list. The gravel contained other mammalian fossils, including portions of the teeth of a *Stegodon* (a Pliocene form of elephant), hippopotamus, rhinoceros, *Cervus*, and a beaver. Taking the latest of these animals as a guide to the antiquity of the deposit, the latter is assigned to the earliest Pleistocene period. It is thus not far removed from the deposit which yielded the jaw referred to *Homo heidelbergensis.* Flint implements were found at Piltdown, but cannot be regarded as a reliable means of dating the bones. Much discussion has taken place since the first publication (in 1912) of an account of this find, and objection has been taken chiefly to the mode of reconstruction of the skull as first exhibited. Some authorities doubt the correctness of associating the various fragments as parts of one skeleton. Consult Dawson and Smith Woodward, "The Piltdown Man," in *Quarterly Journal of the Geological Society*, vol. lxix (London, 1913). Prof. J. H. McGregor, of Columbia University, has made an independent study of these finds and has restored the missing parts as shown in Fig. 2.

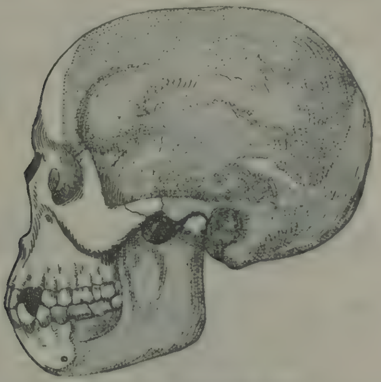

FIG. 2. THE PILTDOWN SKULL.

Eoanthropus (*Homo*) *dawsoni*, Woodward, as restored by McGregor. Drawing one-fourth actual size. Darker portions are parts actually known, lighter parts restored. In lower jaw the darker part is known on the right side.

4. *Galley Hill* (*Northfleet, Kent, England*).—This locality gives its name to a human skeleton discovered in a gravel pit in the year 1888, but not described scientifically until 1895. Many parts of the skeleton were preserved. With the exception of some features of inferiority in the lower jaw and possibly in the teeth, the bones of this skeleton tally exactly with those of existing Europeans. The skull is much distorted, probably through pressure. The conditions under which the bones were collected do not warrant the very important step of assigning this skeleton to the early epoch (in the Pleistocene) at which the gravel bed was deposited. Consult E. T. Newton, "On a Human Skull and Limb Bones Found in the Palæolithic Terrace-Gravel at Galley-Hill, Kent," in *Quarterly Journal of the Geological Society*, vol. li (London, 1895), and for recent criticism, W. L. H. Duckworth, in *Essays and Studies Presented to William Ridgeway* (Cambridge, 1913).

5. *Ipswich.*—A human skeleton found about 4 feet beneath the surface. The skeleton was in a contracted attitude and lay beneath bowlder clay just where this rested upon an underlying sandy stratum. The discovery was made by workmen in the employment of Mr. Moir, of Ipswich. Mr. Moir believes that the skeleton was placed in situ before the deposition of the bowlder clay, and that it represents a human being of greater antiquity than that deposit. The skeleton is of a modern type, but a shin bone which has been preserved is curiously formed, having an oval instead of a triangular section near its mid-point.

The contracted attitude suggests a neolithic interment, but Mr. Moir urges strongly that no evidence of disturbance of the soil could be detected above the skeleton.

From the geological side objections are raised to the effect that the superincumbent clay is not the real bowlder clay as originally deposited, but a wash from the real bowlder clay which is admittedly close by the site on which the skeleton was found. Such a wash may contain all the constituents of the parent deposit, but yet own a much more recent date.

On the whole, it will be discreet not to accept the authenticity of the Ipswich sub-bowlder clay without a great deal more direct evidence than is available at present. Consult Moir and Keith, "Account of the Discovery and Characters of a Human Skeleton Found beneath a Stratum of Chalky Boulder Clay near Ispwich," in *Journal of the Royal Anthropological Institute of Great Britain and Ireland*, vol. xlii (London, 1912).

6. *Olmo.*—A small town in the Val d'Arno (Tuscany) has provided a name for a human skull found in a railway cutting and 50 feet below the surface. The discovery was made in 1863. The associated fossil animals indicate a Pliocene antiquity of the strata. The skull is much elongated, but is of the modern human type. A good cast may be seen in the Museum of Prehistoric Archæology, Château Saint-Germain, Paris. The original is at Florence. The evidence concerning the position and surroundings of this skull is not sufficiently precise to justify its acceptance as a well-authenticated case of an early human fossil. Consult A. H. Keane, *Ethnology* (2d ed., Cambridge, 1896; reprinted, 1901).

7. *Castenedolo* (*Italy*).—Remains of four individuals from strata of undoubted Tertiary antiquity. Though the Italian anthropologist Sergi stoutly defends the claims of the human bones to a similar antiquity, and though his French colleague De Quatrefages admitted the association, the evidence does not seem to be conclusive. All the skeletons are of the modern type. Consult A. H. Keane, *Ethnology* (2d ed., Cambridge, 1896; reprinted, 1901).

8. *Foxhall.*—A human lower jaw, from a coprolite pit at Foxhall in Suffolk. The condition of the specimen suggested great antiquity, but conclusive evidence is lacking. The specimen is of the modern type. Consult R. H. Collyer, "Fossil Human Jaw from Suffolk," in *Anthropological Review*, vol. v (London, 1867).

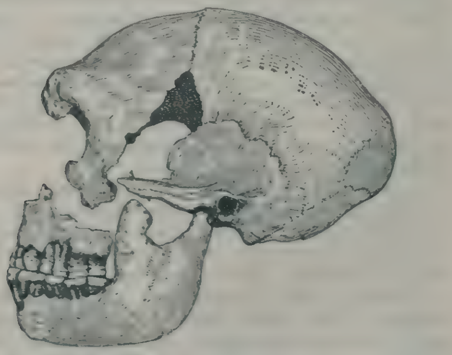

FIG. 3. THE SKULL RECOVERED WITH SKELETON, 1911, FROM LA QUINA, CHARENTE, FRANCE.

9. *Savona.*—A fragmentary human lower jaw of modern type from a Pliocene deposit at Savona in Italy. Conclusive evidence of the great antiquity of this fragment is lacking. Consult Arturo Issel, "Résumé des recherches concernant l'ancienneté de l'homme en Ligurie," in *Congrès International d'Anthropologie et d'Archéologie Préhistoriques*, vol. i (Paris, 1868).

10. *La Quina* (*France*).—This site is very extensive, and it has yielded remains of about nine individuals, most of these being represented by small fragments of their skeleton only; but in September, 1911, Dr. Henri Martin, who is excavating the site, came upon a nearly complete skeleton. This is referred to in publications as H 5 and, speaking generally, it is to be understood that H 5 is indicated where mention is made of La Quina.

The photograph gives a good idea of the skull of an example of *Homo primigenius*. The question of the sex of the individual is still in doubt, though it is more probably female.

Figures 4 and 5 illustrate the methods employed in comparing various skull forms. Thus, in Fig. 4 an outline tracing from the La Quina skull is compared with similar tracings from the *Pithecanthropus* (where the cranial arc is even less developed) and a modern Arab skull, which shows the enormous advance in the evolution of the modern brain case and the vaulting of the skullcap. Besides the skeleton designated H 5, the site at La Quina furnished a very well-preserved half a mandible of *Homo primigenius*. The occurrence of the latter in deposits referred to the end of the Mousterian period is important inasmuch as it illustrates, or helps to illustrate, the range in time of this particular type. The skeleton and skull described above are of much earlier date, though still Mousterian. Consult various publications by Dr. H. Martin, especially in *Bulletin de la Société Préhistorique de France* (Le Mans, 1911), and R. Anthony, "L'Encéphale de l'homme fossile de La Quina," in *Société d'Anthropologie de Paris, Bulletin et Mémoire*, vol. iv (6th series, Paris, 1913).

In conclusion it should be noted that no evidence exists to show that the skeleton at La Quina had been interred. The circumstances suggest that the individual was drowned, for the bones lay in a fine silt deposit, apparently once the bed of a stream.

11. *Le Moustier* (*France*).—A human skeleton discovered in the lower rock shelter of Le Moustier (Dordogne, France). The find was made by Professor Hauser, and the skeleton has been distinguished as *Homo mousterensis hauseri*. The individual was miniature (16 to 19 years of age) and had been interred. The bones were very fragile, but from measurements of these a stature of about 4 feet, 11 inches has been inferred. The skull is of the type of *Homo primigenius* and of large capacity, though this was at first greatly overestimated. The mandible in particular confirms the association of *Homo mousterensis hauseri* with other specimens of the species *Homo primigenius*. Further confirmation is provided by the limb bones. Consult Klaatsch and Hauser, "Homo mousterensis hauseri," in *Archiv für Anthropologie*, vol. xxxv (Brunswick, 1909).

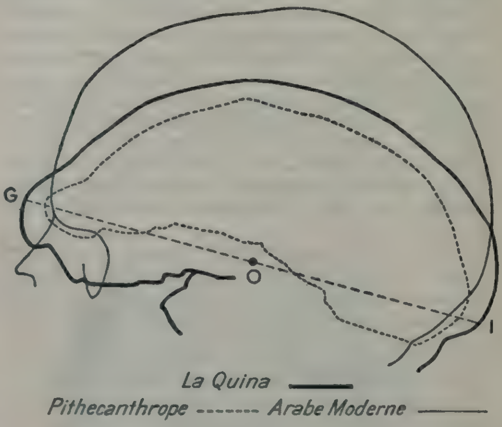

FIG. 4.

Outline tracing of the La Quina skull compared with corresponding tracings from the calvaria of *Pithecanthropus*, and an Arab skull of modern date.

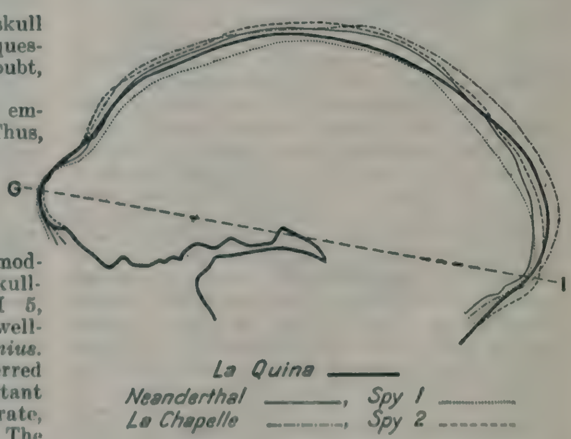

FIG. 5.

Outline tracings to show the concordance in form of the La Quina skull and other examples of *Homo primigenius*.

12. *La Chapelle-aux-Saints* (*France*).—The

skeleton from La Chapelle-aux-Saints is, on the whole, the most complete of all those that are referable to *Homo primigenius*. The body had been interred, and at the time of its discovery in 1908 this was the only example of *Homo primigenius* in regard to which the precise antiquity of the type and the current mode of disposal of the dead could be demonstrated. The skeleton lay on its back in a slight depression. This had been sunk in the floor of a very low cave. Stone implements were found near the bones, with which they are supposed to have been interred. The chief characters of the skeleton have been described incidentally earlier in this article, for the completeness of the skeleton at La Chapelle-aux-Saints makes it the standard to which other more fragmentary remains are to be referred. To take a single instance for illustration, the similarity in respect of the curve of the brain case in the skulls from La Chapelle-aux-Saints, La Quina, and in other examples of *Homo primigenius* may be selected. The closeness of the resemblance in this respect may be understood easily from the comparison of the tracings grouped together in Fig. 5, page 756 (in connection with the notes on the La Quina skeleton). Consult Marcelin Boule, "L'Homme fossile de la Chapelle aux Saints," in *Annales de Paléontologie* (Paris, 1911–13), and G. Schwalbe, "Kritische Besprechung von Boule's Werk mit Eigenen Untersuchungen," *Separatabdruck aus der Zeitschrift für Morphologie und Anthropologie*, vol. xvi (Stuttgart, 1914).

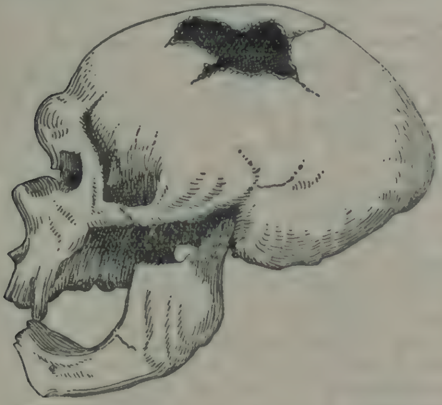

FIG. 6. SKULL FROM LA CHAPELLE-AUX-SAINTS.

13. *Neanderthal* (*Germany*).—A fragmentary skeleton found in a cave (the small "Feldhofer Grotte") in the year 1856. The bones were not seen in situ, but there are some indications that this instance was one of an interment similar to that at La Chapelle-aux-Saints.

The problem of the Neanderthal man has excited attention and aroused controversy for nearly half a century. The earlier work of Schaaffhausen, excellent though it was, needed revision, which was admirably furnished by Professor Schwalbe in 1901; but the value of the specimen and of the descriptions has been increased again since the latter date by the discovery of the other skeleton here described. It goes without saying that the skeleton of the Neanderthal man is typical of *Homo primigenius*, for which form *Homo neanderthalensis* is a synonym. Unfortunately no parts of the face or lower jaw of the Neanderthal skeleton were preserved. The skull is of considerable capacity, very thick-walled, and distinguished by the heavy brow ridges and the receding frontal bone so frequently mentioned above. The limb bones are remarkably massive, with large articular ends, and the shaft of the thigh bone is somewhat distinctly curved. Consult D. Schaaffhausen, "On the Crania of the Most Ancient Races of Men," in *Natural History Review*, vol. i (London, 1861), and G. Schwalbe, "Der Neanderthalschadel," in *Bonner Jahrbucher* (Bonn, 1901).

14. *Forbes Quarry* (*Gibraltar*).—An imperfect human skull discovered in Forbes Quarry by Lieutenant Flint in the year 1848. This is the earliest discovery on record of a skull of the type of *Homo primigenius*, but its interest was quite ignored until 1864, when the specimen was seen (in the museum at Gibraltar) by Dr. Busk. No detailed description appeared until 1907, when Professor Sollas, of Oxford, investigated the characters of the face and the base of the skull. These parts were lacking in the Neanderthal specimen, and at that date the more perfect specimens from La Quina and La Chapelle-aux-Saints were still undiscovered.

Among the numerous important details upon which the Forbes Quarry skull provides information, the small size of the brain case deserves special mention. So marked is this inferiority when the skull is compared with that from La Chapelle-aux-Saints that it has been suggested that the Forbes Quarry skull is of an earlier type than *Homo primigenius*. But the discovery of the La Quina skull (also of small capacity), and the reflection that these small skulls may be those of female examples, lead to the conclusion that they are best retained as of the type of *Homo primigenius*, until better evidence to the contrary effect has been obtained. Practically nothing is known as to the surroundings of the Forbes Quarry skull when found, nor are any other parts of this skeleton preserved. Consult W. J. Sollas, "On the Cranial and Facial Characters of the Neanderthal Race," in *Philosophical Transactions of the Royal Society*, vol. cxcix (series B, London, 1907), and G. L. Sera, "Sul significato della platicefalia con speciale considerazione della razzi di Neanderthal," in *Archivio per l'Anthropologia e per la Ethnologia*, vol. xl (Florence, 1910).

15. *Spy* (*Belgium*).—Fragmentary remains of two skeletons found in a cave in the year 1886. Portions of the skullcap were found, as were also some parts of the facial skeleton of the individual distinguished as Spy No. 1. The skeletons are referable to the type of *Homo primigenius*, but some slight deviations have been remarked. These differences may be, perhaps, significant in view of the fact that the Spy skeletons are referred to a somewhat later period than the typical examples of *Homo primigenius*. Consult Fraipont and Lohest, *Archives de Biologie*, vol. vii (1887).

16. *Krapina* (*Croatia*).—A very remarkable collection of fragmentary skeletons found in a rock shelter on the bank of the river Krapinica in Croatia. The first specimens were discovered in 1899, but Prof. G. Kramberger continued work for some five or six seasons before exhausting the deposit. The large number of individuals and the extremely fragmentary character of the bones, together with the presence of very primitive implements and remains of *Rhinoceros mercki*, confer a most peculiar and mysterious

character on the Krapina rock shelter. Not less impressive is the occurrence of several human types or at least varieties. Thus, it is claimed that while some of the bones are clearly referable to *Homo primigenius*, yet these are not all alike, and it is said that they include specimens necessitating the recognition of a special variety (viz., *Krapinensis*) of that type. The other examples resemble the specimens found at Spy; but again, certain long, slender limb bones were found. The length and proportions of these do not accord with the standard examples of *Homo primigenius*, and it is suggested that at Krapina the skeletons of *Homo primigenius* and the more highly developed *Homo sapiens* are intermixed. Such an association would be more intelligible if the antiquity of the contents of the Krapina rock shelter were proved to be less than that assigned to the Neanderthal and La Chapelle skeletons, for in that event Krapina might provide evidence of an early contact of two types, of which one above (*Homo sapiens*) was destined to survive; but the evidence of the stone implements (and of the rhinoceros bones) is entirely against any attempt to assign such relatively late antiquity to the human remains. Thus, the Krapina rock shelter has provided a problem which cannot be solved satisfactorily at present.

A point worth mentioning is the curious conformation of some of the teeth found at Krapina. A very great number of teeth were obtained. Those in question are molar teeth, and their peculiarity resides in the fusion of their roots. Such fusion gives a very distinctive character to the tooth in which it occurs, and the interest is enhanced by the discovery of similar teeth in a cave in Jersey (St. Brelade), together with implements and animal remains assigning the human remnants to Mousterian antiquity. Consult G. Kramberger, *Der paläolithische Mensch von Krapina* (Wiesbaden, 1906).

17. *La Naulette* (*Belgium*).—A lower jaw found in a cave in Belgium in or about the year 1866. At the time of its discovery it was regarded as the most pithecoid human fossil then known; in fact, some authorities described it as part of the skull of an ape. In this way the Naulette jaw provided a basis for controversies which are still of interest in relation to the analogous instances of the Mauer and Piltdown lower jaws.

At the present time the Naulette jaw is regarded definitely as exemplifying the type of *Homo primigenius;* but though relatively stout, the jaw is smaller than some of those from Krapina and than the jaw of the skeleton from La Chapelle-aux-Saints. The remarks made in connection with the small capacity of the Forbes Quarry skull are relevant in this connection also. Consult C. C. Blake, "On a Human Jaw from the Cave of La Naulette," in *Anthropological Review*, vol. v (London, 1867), and Otto Walkhoff, "Die diluvialen menschlichen Kilfer Belgiens," in Emil Selenka, *Studien*, part ii (Wiesbaden, 1903).

18. *Malarnaud* (*France*).—An imperfect human jaw found in 1888. In general form the Malarnaud jaw closely resembles that from La Naulette and does not demand any detailed description. A point of interest is found in the fact that the Malarnaud jaw lacks the sockets for one of the front (incisor) teeth. This suggests that the tooth had been lost at an early date, perhaps by artificial interference. This suggestion is based on the analogous case of the lower jaw of the Galley Hill skeleton. In the latter instance Mr. Jackson considers that evidence is present of the custom of artificial removal of teeth and of the antiquity of this rite, now found in certain savage tribes only. Consult Malarnaud Filhol, *Bulletin de la Société d'Anthropologie de Paris* (Paris, 1888).

19. *St. Brelade* (*Jersey*).—The human remains thus designated come from a cave in Jersey, where they were accompanied by implements and animal remains referable to the Mousterian epoch. The only point deserving of notice is the occurrence of teeth with fused roots and resembling those found previously in the rock shelter at Krapina only. In this instance the teeth suffice to indicate the former presence (in the Jersey cave) of *Homo primigenius*. Consult R. R. Marett, "Pleistocene Man in Jersey," in *Archæologia*, vols. xii, xiii (2d series, Oxford, 1911–12), and Keith and Knowles, "Description of Teeth of Palæolithic Man from Jersey," in *Journal of Anatomy and Physiology*, vol. xvi (London, 1911).

20. *La Ferrassie* (*France*).—A human skeleton was found in a rock shelter in this locality during the autumn of 1909 by M. Peyrony. The bones were so placed as to indicate that an interment had taken place. Subsequently the fall of blocks of stone from the roof of the shelter had damaged the skeleton greatly. The bones were transported to Paris and have since been very carefully disengaged. When restored this skeleton will add another important document to the list of those illustrating the osteology of *Homo primigenius*. No detailed account is as yet available. It should be added that the excavation of this rock shelter at La Ferrassie has yielded evidence of the most precise kind regarding the succession and superposition of paleolithic deposits from the Acheulian stage onward. Consult Capitan and Peyrony, in "Deux squelettes humains au milieu de foyers de l'époque mousterienne," in *Bulletin de la Société d'Anthropologie de Paris*, vol. i (6th series, Paris, 1910).

21. *Pech de l'Aze* (*France*).—This locality yielded to the excavation of M. Peyrony the skull of a child referable to the period and presumably to the type of *Homo primigenius*. No detailed description is accessible to the present writer, but an excellent description of a young skeleton of *Homo primigenius* has been provided by Herr Hillebrand, who points out several distinctive features even in immature representatives of this ancient human type. Consult Hillebrand, in *Congrès International d'Anthropologie et d'Archéologie Préhistoriques* (Geneva, 1912), and reference under La Ferrassie above.

22. *Taubach* (*Saxe-Weimar, Germany*).—From this region two human molar teeth of unusual form were obtained in 1895. One of these teeth is a "milk" molar, chiefly remarkable on account of its large dimensions. The other tooth is a molar of the permanent series and is distinguished rather by its form and proportions. These are remarkably pithecoid, but the evidence is not of great weight at present, though it indicates that the site at Taubach may at any time yield human fossil remains of an interest comparable even to that provided by the Mauer jaw. Consult Nehring, in *Zeitschrift für Ethnologie* (Berlin, 1895).

23. *Sipka or Schipka* (*Moravia*).—A frag-

mentary human lower jaw. It is referable to the type of *Homo primigenius.* Consult Otto Walkhoff, in Emil Selenka, *Studien,* part ii (Wiesbaden, 1903), and Obermaier, "Quaternary Human Remains in Central Europe," in *Smithsonian Institution, Annual Report, 1906* (Washington, 1907).

24. *Ochoz* (*Moravia*).—The authenticity of the lower jaw from Ochoz was regarded as insufficient by Obermaier (op. cit.; cf. Sipka above). Nevertheless the specimen is accepted as of the type of *Homo primigenius* by so careful an authority as Schwalbe, but nothing is known of the circumstances under which the find was made (Obermaier; cf., however, Rzehak below). Consult Rzehak, "Der Unterkiefer von Ochos," in *Verhandlungen der Naturforschenden Vereinigung,* vol. xliv (Brunn, 1906).

The following examples, Nos. 25, 26, and 27, are referable to the modern type, viz., *Homo sapiens.*

25. *Moulin Quignon* (*France*).—A human lower jaw of the modern type. The antiquity claimed for this specimen by M. Boucher de Perthes would assign it to an epoch earlier than the Mousterian and consequently than that of *Homo primigenius.* The claims were most carefully investigated by experts before rejection, and the account of the discussions that took place will retain a classical interest in the history of this subject. Consult Hugh Falconer, *Palæontological Memoirs and Notes,* vol. ii (London, 1868).

26. *Dartford* (*England*).—A human skull from a gravel deposit in Kent (England). The skull was found by Mr. Newton, and it has been described by Dr. A. Keith. The type is that of *Homo sapiens,* and the capacity is enormous, amounting probably to about 1800 centimeters. Dr. Keith has referred the specimen to the Acheulian period. If this reference be correct, the existence of *Homo sapiens* at a time when there is no evidence as to the presence of *Homo primigenius* would be established, but the stratigraphical evidence is open to criticism, so that the specimen cannot be regarded as fully authenticated.

27. *Bury St. Edmunds* (*England*).—The fragment of a human skullcap from a gravel deposit near Bury St. Edmunds in Suffolk (England) has been before the public for about 40 years. Dr. Keith has recently achieved a reconstruction of the skull of which the above fragment formed a part. The reconstruction shows a human skull of entirely modern type. The interest of this specimen depends upon the antiquity assigned to it. Thus, it resembles the instances of Galley Hill, Ipswich, Moulin Quignon, Dartford, and others.

By some authorities the Bury St. Edmunds fragment has been assigned to the Acheulian epoch, to a time, that is, when no good evidence as to the existence of even *Homo primigenius* is forthcoming.

The evidence as to the contemporaneity of the Bury St. Edmunds skeleton with the deposition of the strata in which it lay is of the same nature as in those other instances. In none of these is the evidence conclusive, and no multiplication of the number of such instances will strengthen the case for their great antiquity, unless and until the nature of the evidence is altered in the direction of greater conclusiveness. For the present, therefore, it is better to withhold them all from the category of well-authenticated examples. Consult Arthur Keith, *Journal of Anatomy and Physiology* (London, 1913).

In the preceding notes account has been taken of the earliest representatives of humanity, then of *Homo primigenius,* and also of certain examples of *Homo sapiens,* for which great antiquity is claimed in some quarters.

The remaining skeletons (or fragments) mentioned in the table are all undoubtedly referable to the type of *Homo sapiens.* Without exception they were found in caves, and their antiquity is clearly shown and known. They are of later date than the latest deposit, which has hitherto yielded *Homo primigenius,* save in instances where disturbance of deposits of different ages has led to their admixture. The skeletons now to be considered belong for the most part to that division of the Paleolithic period called Aurignacian. One example comes from the succeeding Magdalenian epoch, but all are of Post-Mousterian antiquity.

Although the men of the Aurignacian epoch are always and undoubtedly of the type of *Homo sapiens,* nevertheless there are certain differences, so that distinctions of a racial kind have been drawn. Consequently the notes on skeletons of Aurignacian antiquity fall into three divisions, each corresponding to one of these racial types, while all are included under the general designation of *Homo sapiens.*

A. RACE OF CRO-MAGNON. This is exemplified by the following instances.

28. *Cro-Magnon* (*France*).—The skeleton known as that of the "old man of Cro-Magnon," discovered nearly 50 years ago by Messrs. Christy and Larlet, has provided a name for one of these racial types.

The most prominent characters are the great stature and strength, as evinced by the length and massiveness of the limb bones, the skull being proportionately large. Judged by the skeleton, the men of the Cro-Magnon race have not since their appearance been surpassed as regards physique, no matter what subsequent epoch be selected for comparison.

29. *Paviland* (*South Wales*).—A skeleton (without the skull) found in the Paviland cave in South Wales is identified in type with the Cro-Magnon race. This specimen has an historical interest of very special kind. When found in or about the year 1823, it was supposed to be referable to the Roman-British period, and it was assigned to the female sex. Nearly 90 years were to elapse before its true antiquity was demonstrated. This was done in 1912 by Professor Sollas, of Oxford, so that the skeleton is now to be regarded as that of a man of Aurignacian antiquity, agreeing in stature with the standard examples of the Cro-Magnon race. Consult *Paviland Cave: An Aurignacian Station in Wales,* Huxley Memorial Lecture for 1913, published by the Royal Anthropological Institute of Great Britain and Ireland (London, 1913).

30. *Barma Grande* (*Mentone*).—Two skeletons of the Cro-Magnon type, from the Mentone cave of that name. They have been described by Professor Verneau, of Paris, to whom is due an account of several other skeletons from Mentone.

31. *Cavillon* (*Mentone*).—A skeleton of the Cro-Magnon type. It was found in the Grotte du Cavillon near Mentone, and it was described by Professor Verneau.

B. RACE OF GRIMALDI.

32. *Grotto des Enfants* (*Mentone*).—Two hu-

man skeletons from the very lowest part of the Aurignacian strata in the Grotte des Enfants differ from those typical of the Cro-Magnon race. They must be very particularly distinguished from the skeleton of the Cro-Magnon type which was actually found in this same cave, but at a higher level. Some indications exist to the effect that the two skeletons thus distinguished should be accorded an antiquity greater than that expressed by the term "Aurignacian"; but, though the claims to Pre-Aurignacian antiquity exist, they cannot be conceded as they stand. However this may be, the race of Grimaldi is a conception based on the study of the two skeletons, and its chief claim to interest is that suggestions of the African negro type were met with. The two skeletons had been interred and were found almost in contact with each other. Both were in a contracted attitude, and each had been placed so as to rest on the right side. While admitting the distinctness of the Grimaldi type, it is not held that the negro affinities are in any way proved. Yet even the suggestion of such resemblances must not be ignored. Future discoveries may well elucidate their real significance.

C. RACE REPRESENTED BY HOMO AURIGNACENSIS HAUSERI.

33. *Combe-Capelle (France)*.—A human skeleton from an interment of Aurignacian antiquity at Combe-Capelle has been designated *Homo aurignacensis hauseri*. The latter term commemorates the name of its discoverer, who (it may be noted) also found the young *Homo mousterensis* in the same region.

Homo aurignacensis hauseri is of a racial type of *Homo sapiens* differing from the Cro-Magnon and Grimaldi racial types alike. In the absence of other examples its real affinities must be matters of surmise only; but the narrow and high brain case, together with the form of the orbital and nasal apertures, confer on the skull an aspect strongly reminiscent of certain skulls from New Britain (New Pommern). The present writer is not alone in remarking these characters and the analogy they suggest. The subject has been worked out independently by Professor Mochi, yet the view here taken is that these resemblances are merely hints and suggestions, as in the analogous instance of the Grimaldi skeletons. Consult Klaatsch, "Der neue Skelettfund Hausers aus dem Aurignacien," in *Prähistorische Zeitschrift*, vol. i (Berlin, 1909), and *Zeitschrift für Ethnologie* (ib., 1911).

Of the paleolithic epochs later than the Aurignacian, a single example has been selected for a descriptive note.

34. *Chancelade (France)*.—The human skeleton of Magdalenian (i.e., Post-Aurignacian) antiquity has undoubted analogies with the Cro-Magnon racial type, but in addition an interest of another kind is presented by the alleged Eskimo affinities of this example. It will be remembered that, upon the evidence of the animal remains found in Magdalenian deposits, that epoch has been credited with climatic conditions such as would assimilate the south of France to the present-day conditions of Greenland. That the man of the period should resemble the existing Eskimo is intelligible enough. Moreover, the imagination of some writers enables them to recognize in the Eskimo of to-day the lineal descendants of the Magdalenian Western Europeans. These are supposed to have emigrated when the climate changed.

Such occurrences are quite possible, and in regard to the latter part of the hypothesis, all that can be said is that direct evidence has yet to be presented. But more particularly in reference to the Eskimo features in the skull from Chancelade, it is clear, even from photographs of that specimen, that the identifications rest on the most fragile of foundations. So far as osteological investigations go, there appear to be no good grounds for separating the Chancelade man from the group already described as the Cro-Magnon race. Consult L. Testut, *Recherches anthropologiques sur le squelette quarternaire de Chancelade* (Lyons, 1889).

It is not to be supposed that the foregoing series of notes is at all exhaustive, but under the circumstances it would be impossible to provide intelligible descriptions of even a majority of the instances on record. Consequently a choice had to be made, and it is believed that the notes given here deal with all the more important and typical examples.

LIVING RACES

Nowadays the scientific investigation of human races avails itself of essentially different methods from those of mere description or artificial classification. Since Darwin (1809–82) our era has witnessed a remarkable gain in profundity of method. In this connection must be mentioned the rediscovery of Mendel's laws and their application to biological processes, not merely in the animal and plant kingdoms, but as connected with the human species as well. As the human races represent organic or biological forms, they must be subjected to the specific methods of investigation followed by ontogeny, anatomy, physiology, and physical anthropology. Although these sciences furnish the essential foundations for a possible natural classification of races from a biological point of view, physical anthropology will in addition touch those fields of inquiry connected with the ergology, or culture (q.v.), of human subdivisions. This felicitous term designates all the psychic manifestations of races, such as language, religion, agriculture, industrial life, mode of habitation, etc. However, we must recognize that only physical anthropology is able to determine the somatic and morphological differences of human races and to establish their mutual relations.

Even the oldest cultural monuments extant, viz., the old Egyptian paintings on graves and temples, represent widely differing types of humanity. The separation of these types must have occurred at a period of time immeasurably earlier, a period when man branched off from a highly developed vertebrate type. This fact is important for the comprehension of biological processes. We meet here a fundamental property of organic life, variability, i.e., the ability immanent in organisms to produce alterations in any of their characteristics. The causes of variation include natural or sexual selection, climate, nutrition, social environment, as well as, in all probability, factors as yet unknown. Granting variability, we must assume that from a highly developed vertebrate—a hypothetical paleoprimate—there developed both the anthropoid apes and a being representing man's ancestor. The latter, in the course of its further development, originated the morphological peculiarities distinguished as human in contradistinction from those of the most nearly allied vertebrates, the anthropoids. We must vigorously oppose the view often met with in lay circles that man developed directly from the anthropoids. The morphological peculiarities referred to consisted in the larger head and the consequent increase in the size of the brain. With higher ideational processes there developed a specialization in the use of the frontal extremities and the upright gait, and articulate speech arose, connecting phonetic symbols with ideas. However, a second element of basic significance must be mentioned—heredity. Alterations are effective in the production of an organic form only in so far as they are inherited. In order that a new species should originate, it was a prerequisite that the effects of selection, of the struggle of existence or environmental factors, should be inherited. Whether man originated in a single spot (monogenetically) or in several distinct places (polygenetically) is a question that has lost significance compared with the study of the conditions of human development. More attention should be devoted to the problem whether the same unknown factors that determined the origin of the new human species also effected the differentiation of morphologically and somatologically distinct races, and to what extent additional influences were responsible for this phenomenon. Science is attempting to solve this puzzle by various experimental researches. The comparative studies of Mollison on serum, of Friedenthal and G. Retzius on sperm cells, of Mollison on the color sense have already furnished results that form a basis for future work. Presumably the changes produced in plants and animals by experimental influences due to changes in light, heat, and food may be applied to the human problem.

If the inheritance of specific traits is a condition of the origin and propagation of a species, the same rule holds for subdivisions of a species, i.e., the varieties. These may be called races. "A race," says Rudolf Martin, "is a constant variety of a species." The external, readily discernible criteria of races are the starting point of even the oldest attempts at racial description. Naturally this also applies to modern investigation, however different may be the novel points of view assumed.

The main criteria to be considered are: (1) the form of the hair; (2) pigmentation of the skin, hair, and iris; (3) the form of the skull, including not merely the ratio of breadth and length (or cephalic index), but absolute measurements of the face and brain case, as well as skull texture and capacity; (4) physical size and the bodily proportions; (5) physiognomic traits, such as the ear, nose, lips, eyelids; (6) the soft parts, such as muscles, nerves, vascular elements; and the phenomena amenable to physiological experimentation.

On the basis of these criteria various systems of classification have arisen which may be distinguished as natural and artificial. Among the latter may be mentioned the classification of A. Retzius (1796–1860) and his followers, who distinguish orthognathous and prognathous longheads (dolichocephali) and orthognathous and prognathous shortheads (brachycephali), thus relying only on the form of the skull. Kollmann makes additional use of the form of the face, dividing mankind into broad-faced and narrow-faced types, each subdivided according to short, long, or intermediate character of the skull; these six categories are again subdivided according to the smooth, curly, or frizzy nature of the hair. In this connection may be mentioned Fr. Müller (1834–98), whose system serves as an example of a mixed morphological and cultural basis of classification. He distinguishes woolly and smooth-haired varieties with minor subdivisions based on linguistic types. The natural systems are based on differences in pigmentation. Thus, Linnæus (1707–78) recognized *Homo europæus, asiaticus, afer* (*africanus*), and *americanus;* Blumenbach (1752–1840) distinguishes the Caucasian, Mongolian, Ethiopian, American, and Malayan varieties; Cuvier (1769–1832), Broca (1824–80), and Topinard (1830–1911) divide mankind into the white, yellow, and black races; while Huxley (1825–95) recognizes Australoid, Negroid, Xanthochroic (blond), and Mongoloid types, to which he adds the Melanochroic group (dark South Europeans) as a hybrid variety.

All the above-mentioned classifications are far too schematic. We are indeed in need of general terms for the large homogeneous groups of humanity. However, a rational system must start from the composition of human groups and seek to determine their relations to pure types, an arduous task far from completion. It is entirely unjustifiable to base classification on a single morphological or somatic trait. It is worse to classify according to cultural factors, such as speech, religion, or social customs, for the core of the problem remains untouched by these ethnological criteria, which have nothing to do with physical characteristics. Any system will meet with better success that shall establish racial groups according to their general morphological features. Thus, Deniker's classification is based on a joint consideration of the form of the hair, skin color, form of the nose, head form, and stature. There is no division into main branches corresponding to those of the authors mentioned above. Deniker establishes six groups according to the criteria named and subdivides these into 29 races, to wit:

A. WOOLLY HAIR, BROAD NOSE
  1. Bushmen
  2. Negrito
  3. Negro
  4. Melanesian

B. CURLY OR WAVY HAIR
  5. Ethiopian
  6. Australian
  7. Dravidian
  8. Assyroid

C. WAVY BROWN OR BLACK HAIR, DARK EYES
  9. Indo-Afghan
  10. Arab or Semite
  11. Berber
  12. Littoral European
  13. Ibero-insular
  14. Western European
  15. Adriatic

D. FAIR, WAVY OR STRAIGHT HAIR, LIGHT EYES
  16. Northern European
  17. Eastern European

E. STRAIGHT OR WAVY HAIR, DARK, BLACK EYES
  18. Ainu
  19. Polynesian

  20. Indonesian
  21. South American
F. STRAIGHT HAIR
  22. North American
  23. Central American
  24. Patagonian
  25. Eskimo
  26. Lapp
  27. Ugrian
  28. Turkish or Turco-Tatar
  29. Mongol

Each of these varieties is characterized according to bodily traits, although *named* in part after merely national groups; they are therefore genuine racial subdivisions.

There have been some attempts to establish a racial classification by creating a nomenclature according to zoölogical principles. Of these, only those of Wilser and Sergi need be mentioned. Wilser distinguishes his largest groups as zoölogically distinct species, which are subdivided into varieties.

A. *Proanthropus erectus* (*Pithecanthropus dubois*).

B. *Homo primigenius.*

C. *Homo europæus* (*Homo europæus* var. *fossilis* [Cro-Magnon], *Homo europæus* var. *mediterranea* [var. *fossilis* (Brunn, Brux, etc.)]).

D. *Homo niger* s. *afer* (var. *fossilis* [Grimaldi], var. *australis, etc.*).

E. *Homo brachycephalus* s. *asiaticus* (var. *fossilis* [Grenelle, Furfooz, etc.], var. *alpina*, var. *americana, etc.*).

Sergi's system is probably the one best adapted to modern demands, though his derivation of the European race from Central Africa is unacceptable. He divides all humanity, both living and extinct, into five genera, subdivided into species and varieties. The following gives a compact presentation of his views:

A. PALÆANTHROPUS (extinct)
  1. *Palæanthr. europæus* (Neanderthaler, etc.)
  2. " *krapinensis*
  3. " *heidelbergensis*
B. ARCHÆANTHROPUS (extinct)
  1. *Archæanthr. pampæus* (La Tigra, etc.)
C. NOTANTHROPUS (notos = south)
  1. *Notanthr. eurafricanus*
    a. *Not. eurafr. nordicus* (Sweden, Norway)
    b. " " *africus* (Abyssinian, Galla, etc.)
    c. " " *dravidicus*
    d. " " *polynesianus*
    e. " " *tod-ainu*
    f. " " *mediterraneus*
    g. " " *medit. europæus* (southern Italy)
    h. " " " *libycus*
    i. " " " *arabicus*
    j. " " " *egyptianus*
    k. " " " *indoiranus*
  2. *Notanthropus afer*
  3. " *australis* (Hottentots)
D. HEOANTHROPUS (eos = east)
  1. *Heoanthr. eurasicus*
    a. *Heo. euras. europæus* (Great Russians)
    b. " " *asiaticus* (until now known as *alpinus*)
  2. *Heoanthr. arcticus*
  3. " *orientalis*
E. HESPERANTHROPUS (hesperos = west)
  1. *Hesperanthr. columbi* (American Indians, Eskimo)
  2. " *patagonicus*

In short, there is no dearth of racial classifications. However, the grouping of the human material in these divisions forms a very intricate problem, for the groups found by the student represent a highly mixed product of the species *Homo.* We must go back very far indeed to meet with a group of relatively unmixed representatives of a single race; indeed, many deny the existence of pure races.

Racial diagnosis in cases of mixture is greatly aided by the Mendelian laws of inheritance, which after a period of complete neglect have recently been rediscovered and proved their usefulness in an astonishing manner. Mendel holds that parental traits are inherited in succeeding generations in a definite proportion of cases, so that hybridization results in a certain constancy of the traits. From this point of view the racial problem is simplified in an objective way. Several scientists, e.g., E. Fischer in his excellent studies of the Hottentot bastards, have already applied Mendelian conclusions to racial investigation. Fischer corroborates the rule that mixture of two distinct races never effects the origin of a new race. The traits of the two races are inherited independently, i.e., the traits of the one persist and combine with those of the other. Thus there may result an increasing host of traits in combination. In order to investigate these, new statistical methods have been developed (especially by Karl Pearson), leading to the science of biometry. However, there never develops a new race. On the contrary, each race reverts to its original type, a process of "demiscegenation" (*Entmischung*), to use Von Luschan's term.

The means employed in racial study include (*a*) observations of dead material, including both skeletal remains and soft parts; (*b*) observations of living individuals (somatology, bodily proportions, physiology); (*c*) socio-anthropological investigations on the influence of locality, diet, labor, and social condition. To these must be added the abstract treatment of heredity by statistical study and the methods of experimental biology as applied to men. Thus, Walcher has attempted to produce arbitrarily short-headedness or long-headedness by consistent treatment of infant skulls. The influence of environmental conditions seems to be indicated by Boas's studies on the American-born children of East European Jewish, Neapolitan, and Sicilian immigrants. He discovered that the brachycephalous Jewish children were not so short-headed, and the dolichocephalous Italian children not so long-headed, as their parents, both approaching an intermediate mesocephalous type.

A brief summary of the status of racial investigation in the grand divisions of the globe will be given presently. Stress must be laid on the fact that so far we have made only a fair start towards the solution of the problems, whether centring (1) in the determination of the number and distribution of racial types or (2) in their relations to the prehistoric races and one another, from both a purely biological and an ethnological point of view. Detailed considerations as to the persistence and disappearance of races cannot be made in this general article.

Europe. Deniker has industriously compiled data on the distribution of racial traits. He recognizes six European races, with specific zones of distribution: (1) *Northern race*, tall, blond, light-eyed, long-headed, narrow-faced, with narrow, straight nose; (2) *Eastern race*, of shorter stature, with broader face and nose; (3) *Western Alpine race*, short, brown, very short-headed, with round face and broad nose; (4) *Ibero-insular* or *Mediterranean race*, dark-brown, short, dark-skinned, with narrow, straight nose; (5) *Coastal* or *Atlanto-Mediterranean race*, of tall or medium stature, mesocephalic, dark; (6) *Adriatic* or *Dinaric race*, very tall, very short-headed, dark, with straight or convex nose. Of these groups, Nos. 1, 3, 4, and 6 are generally recognized. Scientists assume that the home of the blond race lies in the north. The Asiatic origin of the Alpine race is regarded as fairly certain, though the occurrence of short skulls in diluvial times leads some, e.g., Giuffrida-Ruggeri, to champion an independent development of shortheads in western Europe. Opinion is divided as to the Mediterranean race, which some scholars view as an independent Southern group, while others regard it as a branch of the North African race, mixed with elements from Asia Minor. Still others hold that it is a branch of the Northern race that has become darker and shorter and unite it with the Dravidians of India (E. Fischer). The Dinaric race points to a connection with Asia Minor, i.e., with Von Luschan's Armenoids. On this hypothesis the distribution of the Armenoid type would extend to central Europe. In quite recent times efforts have been made to identify certain head forms with various old cultural epochs (Schliz).

Asia Minor. Von Luschan assumes Armenoid aborigines whose presence dates back at least to the second pre-Christian millennium. The Hittites are assuredly an integral portion of the autochthonous population. They are characterized by an extremely flat occiput and a crudely hooked nose. In the ninth century B.C., Semitic tribes immigrated and blended with the natives. From the valley of the Danube came a third element, the Amorites, whose tall stature and light hair point to a relationship with the Northern race. To their influence Von Luschan ascribes Semitic blondness. The racial composition of the Semites has not been satisfactorily ascertained. There are short-headed elements, represented by the Askenassi, and long-headed elements, such as the Sephardim. These differences, coupled with those of the color and form of the hair, point to a complex racial composition.

Africa. In northern Africa anthropology must deal with the Egyptians, Berbers, and Guanchos. The Egyptian question is of special interest because its development may be traced back to predynastic times by means of the skeletal material extant, the oldest dolichocephalous skulls being gradually supplanted by mesocephalous heads. A blend with foreign types is indicated by Negroid and short-headed (Asiatic) elements. In northwestern Africa the occurrence of the blond blue-eyed type points towards a mixture of Berber and North European types. The Guanchos of the Canary Islands display points of contact with the Berbers and the Egyptians, as well as with the Iberians and the prehistoric Cro-Magnon type.

In the remainder of Africa the racial relations are likewise highly complicated and far removed from solution. Probably the Pygmies were originally distributed over the entire continent. Their relations towards the Bushmen are still quite obscure. All we know is that steatopygous Pygmies (i.e., possessing the abnormal development of the gluteal region found among the Hottentot) were known to the ancient Egyptians, and that plastic representations extending to Crete, Austria, and France date back to the Stone age. The same applies to the Bushman-like cave paintings of the Stone age, which occur in Tunisia, France, and Spain, resembling those in South Africa. The position of the Pygmies in regard to the primitive Negro population of Africa remains an unsolved problem. The two large linguistic groups, Bantu and Sudan Negroes, embrace so many distinct anthropological types that no definite statement can be given regarding their interrelations. The purest form of Negro type seems to occur on the Guinea coast, while the Bantu seem to have been changed appreciably by North African and Northeast African races.

Malay Archipelago and South Seas. The racial conditions of the Malay Archipelago are fairly clear, owing to the anthropological labors of the Sarasin cousins, Rudolf Martin, Hagen, and Moszkowski. The lowest stratum is represented by the Vedda of Ceylon, Toala of Celebes, Senoi of central Malacca, Kubu and Sakei of Sumatra, and the Kha, Mai, and Penong of the Indian mainland. This genuinely autochthonous race probably occupied the territory prior to the geological separation of the Malayan islands. A second layer represented only by survivals is constituted by the Semang, Andaman Islanders, and Philippine Negrito. It probably extends to the Papuas, and there may be some connection with the African Pygmies. Finally, there are the Malays of the earlier type (Battak, Dayak, Igorot) and of a later period (Coast Malays, Javans). The racial relations of Oceania are obscure. Those of the Australians have become better known through Klaatsch's excellent papers describing their "pre-Neanderthaloid" traits.

Asia (exclusive of Asia Minor). The physical anthropology of this continent is relatively little known, though the work of Japanese scholars, such as Koganei and Adachi, is of great value. The Ainu seem to represent a primitive Japanese stratum, with relations to the Indo-Germanic type and points of contact with the Australians. The Japanese may be divided into a cruder and a more refined type, the former suggesting southern China, while the latter rather points to the Northern Chinese. China is practically a terra incognita, and the connection of Mongolian and European races is likewise obscure. The same must be said of the racial interrelations of India and the connection of the Indians with Europeans, though significant resemblances occur.

America. So far there is no clear evidence of man's existence in America before or during the Glacial period. The specific form of the American variety developed in that continent, but it remains unsettled whether anthropological relations connect it with the races of other grand divisions. For the Eskimo, Asiatic connections seem definitely proved. Their Mongolian traits suggest an origin beyond Bering Strait. For the Indians such a hypothesis is far from being demonstrated. Ehrenreich affiliates them, in spite of the Mongoloid features they display, with the Caucasians. There certainly is a very great multiplicity of types distributed over North and South America. Hrdlička enumerates both long-headed and short-headed groups, and the study of South American aborigines points to the existence of several distinct anthropological layers. American Indian traits include the uniformly straight hair, which has a nearly round cross section; a large and projecting nose; a greater than Caucasian degree of prognathy; prominent zygomatic arches; small hands and feet; and a fair muscular development. Culturally the American natives have not been purely passive, but have spread their own culture, as was shown in the course of the Jesup expedition.

The question of the development of a specifically modern (white) American type due to adaptation to modern American environmental influences will have to be settled in the future. The same applies to moot problems discussed under the title eugenics (q.v.), by which is meant the deliberate selection of mates for the procreation of physically and morally perfect individuals.

In place of statistical census data on the races we are unfortunately obliged to rely on estimates of conjectural value. The number of Mongolians is set at from 500 to 600 million; that of Europeans (including the four races specified above) at from 600 to 700 million; that of African Negroids at from 100 to 120 million.

Bibliography. For a classification of races, consult: J. Deniker, *The Races of Man* (London, 1900); A. H. Keane, *Ethnology* (2d ed., Cambridge, 1896; reprinted, 1901); A. C. Haddon, *The Races of Man* (London, 1912); Giuffrida-Ruggeri, *Homo sapiens* (Vienna, 1913); Rudolf Martin, *Lehrbuch der Anthropologie* (Jena, 1914). The last-mentioned book is a standard up-to-date work with full bibliographies for every phase of physical anthropology. T. H. Huxley's essay "On the Geographical Distribution of the Chief Modifications of Mankind," in *Journal of the Ethnological Society of London*, N. S., vol. ii (London, 1870), is of historical interest. A critical discussion of classification in general is given in Paul Ehrenreich, *Anthropologische Studien über die Urbewohner Brasiliens* (Brunswick, 1897). Among other works of general bearing may be mentioned: W. L. H. Duckworth, *Morphology and Anthropology* (Cambridge, 1904); A. C. Haddon, *The Wanderings of People* (ib., 1911); Ranke, *Der Mensch* (2d ed., 2 vols., Leipzig, 1911–12).

MANABOZHO, măn′ȧ-bō′zhō, NENEBOJO, or MICHABO. The culture hero among some of the Algonquian tribes, e.g., the Menomini; other tribes of this stock venerate the same figure under other names, such as Wisaketcak (Cree). He is represented as the principal agent in the work of creation, the teacher of the various Indian arts of hunting, fishing, and the like, the destroyer of monsters and neutralizer of evil influences, and withal as a great trickster. He is rather a mediator between the supernatural powers and the Indians than a supreme deity himself. In other regions of North America a corresponding figure, presenting the same dual character of hero and clown, appears in the guise of a coyote, raven, etc. For the Algonquian conception consult: Schoolcraft, *The Myth of Hiawatha* (Philadelphia, 1856); W. J. Hoffman, "The Menomini Indians," in *Bureau of American Ethnology, Annual Report, 1892–93* (Washington, 1896); Russell, *Explorations in the Far North* (ib., 1898); Jones, *Fox Texts* (Leyden, 1907); Alanson Skinner, *Social Life and Ceremonial Bundles of the Menomini Indians* (New York, 1913); Paul Radin, *Some Myths and Tales of the Ojibwa of Southeastern Ontario* (Ottawa, 1914).

MANACOR, mä′nȧ-kôr′. A town on the island of Majorca, Spain. It is situated on a small eminence surrounded by a fertile plain, 8 miles from the east coast of the island (Map: Spain, G 3). The town contains a number of ancient buildings, among which is a palace of the old kings of Majorca. It has manufactures of brandy, flour, pottery, and leather; is connected with Palma by rail, but has no great commercial importance. Not far away are interesting caves: that of Drach, containing several underground lakes, and those of Artá, four miles away, forming one of the most spacious and beautiful groups of stalactite caves in western Europe. Pop., 1900, 12,548; 1910, 12,436.

MANAGEMENT, HOME AND INSTITUTION. Considered as a branch of home economics, this treats of the administration of the affairs of a private family or of a larger group of people living together and has to do less with details of housework than with matters of general policy in housekeeping and home making; and though the outlining of plans and the oversight of details fall to the same person in the great majority of homes and often in institution households, the responsibilities connected with them can be separated in thought, and are, indeed, discussed under different heads in technical treatises on home economics and for educational purposes.

The successful management of a home, small or large, presupposes some understanding of available resources in the way of labor, power, and money; certain standards for the work to be performed and ideals for the ends to be reached as the result of family life or coöperative living, and some ability to direct available means towards desired accomplishments. Available labor includes that of members of the household, of hired helpers, permanent or temporary, and, in a broader sense, of persons working for the home in bakeries, laundries, or other places where commodities needed in the household are made or needed services are performed. One duty of the home or institution manager is to decide whether a given piece of work shall be done in the home or outside of it; by members of the household or hired helpers; by adults entirely or partly by children for purposes of training in household arts; directly or by machinery; by hand or other forms of power. Such choices, almost unknown under primitive conditions, present themselves with increasing frequency as factory methods of producing household commodities develop, as specialization extends to new fields and results in separate establishments for cleaning, catering, the care of the sick, and other services previously performed only in the household, and as improvements in communication and transportation (parcel post, rural delivery, telephone) bring isolated homes within reach of markets for commodities and services.

Wider opportunities for choice as to methods are creating a demand for more accurate means of judging and comparing results and for a clearer understanding of the relation of household processes and products to comfort, health, and human needs in general. This demand is being met by the publication of works on the chemistry of food and textiles, household sanitation, hygiene and decoration, and by courses of instruction in all branches of home economics. More important still, standards are being formulated. Score cards have been devised for judging many products—e.g., bread and canned goods. In large institutions and schools studies are being made of the time required for performing various household tasks and of the comparative cost of homemade and commercial articles, and all along the line the tendency is towards standardization of methods and results.

The apportionment of the income of family or institution among the various items of expenditure—rent, food, clothing, recreation, and others—is another function of household management. In estimating income it is necessary to take into account not only the money earned by members of the family or the amount appropriated for the support of the institution, but also the value of commodities produced and consumed in the household—e.g., vegetables or articles of clothing and house furnishing—and the estimation of this part of the income waits in many cases upon a more general agreement as to the value of the home maker's time. In the case of private families particularly agreement is retarded by the fact that as household industries disappear there is a tendency to emphasize the importance of the home as a place where the affections centre, where children are trained and character is developed. There is a tendency, too, to emphasize the home-making features in public institutions, particularly those that care for dependent children or old people. This in many cases makes the services of the manager difficult to measure in terms of money. There is, however, a movement towards the adoption of business methods so far as they are applicable—a fact to which the growing custom of making budgets, i.e., of determining beforehand how the income shall be apportioned and of keeping and interpreting household accounts, testifies.

So great are the possible economies in energy and money where large numbers of people are concerned that institution management has already been placed upon a professional basis, and while the management of a private home has to do with smaller amounts of money and with values more difficult to estimate, it is not far behind in this respect.

Bibliography. L. M. Salmon, *Progress in the Household* (New York, 1906); B. M. Terrill, *Household Management* (Chicago, 1910); I. H. Clark, *Domestic Science* (Boston, 1911); M. B. and R. W. Bruère, *Increasing Home Efficiency* (New York, 1912); E. P. Flagg, *Handbook of Home Economics* (Boston, 1912); C. McG. Frederick, *New Housekeeping* (Garden City, N. Y., 1913); Kinnie and Cooley, *Shelter and Clothing* (New York, 1913); id., *Foods and Household Management* (ib., 1914); T. Q. Franks, *Efficiency in the Household* (Garden City, N. Y., 1914); C. J. Lynde, *Physics of the Household* (New York, 1914); *Spon's Household Manual* (ib., 1915); also publications of the American Home Economics Association (Baltimore, 1899 et seq.) and reports of the Lake Placid Conferences on Home Economics (Lake Placid, N. Y., 1899 et seq.).

MANAGEMENT, Legislative. In industry, a policy and practice of management developed from the "committee system" and still equally well recognized under that name. The aim is to apply the principle of staff guidance without impairing line organization and at the same time to enlarge the viewpoint and enlist the coöperation of directing line officials by methods of suggestion akin to those characterizing the Hine system of unit organization. See Efficiency.

Under the committee system as advocated by C. U. Carpenter in 1908 a general factory committee was formed to consider the most important questions arising in the works and act as advisers to the management. The *personnel* of this committee was so selected as to bring together the ablest and most experienced heads of departments, upon whose harmonious working the general success of the plant depends. These would probably be the chief designer of product, the chief designer of tools, the head of the cost department, and one or two general foremen, under the chairmanship of the superintendent. Thus into one group would be brought men representing knowledge of the kind of product that could be sold, of the kind of equipment necessary for its manufacture, of the cost of manufacturing it, and of the practical execution of the manufacturing operations. Past difficulties, current progress, future possibilities, departmental schedules for the completion of work in hand or to be undertaken, could be discussed and determined by the men certainly responsible for the several phases of the work, and an immediate written record made for reference and comparison at the next stated meeting. With frequent meetings and a consciousness that reports would be required and compared with promises, it was believed that a sense of responsibility would be heightened; while with the sense of a joint share in the success of a department programme, it was believed that a feeling of larger relations and a wider vision of duties would be fostered.

A similar system of committee organization was carried through the lower ranks by subsidiary committees made up of general foremen and minor officials, the idea everywhere being frequent conferences, open discussions, and stenographic or blackboard records for exhibition at the next meeting.

As further developed by C. E. Knoeppel, legislative management shows the influence of some of the doctrines of scientific management (q.v.). Instead of a single comprehensive and general factory committee, certain "functionalized" activities of the plant are recognized and each of these is put under its own committee, the six functional committees thus constituted being coördinated and controlled in their work by an executive committee. The functional activities recognized and provided for are engineering and drafting, planning, conditions, operations, materials, and relations and incentives. The committees separately charged with each of these functions meet regularly or at the call of the executive committee, consider carefully all matters referred to them, and submit their conclusions with the reasons supporting them to the executive committee, by whom they are either accepted and made binding upon line officials or returned to the committee for further deliberation or to staff advisers for investigation.

The several committees, as under the Carpenter system, are made up principally from line officials, thus made also staff advisers, although in Knoeppel's legislative management a representative of the efficiency staff appears in every one of the functional committees. A summary of his suggested choice of *personnel* is appended, the explanatory words in parentheses indicating the interest represented by each member of each committee.

ARRANGEMENT OF COMMITTEES UNDER LEGISLATIVE (FACTORY) MANAGEMENT

Executive Committee: General manager (administrative); chief designer (product); office manager (records and data); treasurer or accountant (finance); superintendent and assistant superintendent (shop); and efficiency engineer (betterment work).

Engineering and Drafting Committee: Sales manager (customers); chief designer (product); superintendent (shop); and efficiency engineer (betterment work).

Planning Committee: Superintendent (shop); purchasing agent (materials); foreman of department affected (individual department); and efficiency engineer (betterment work).

Conditions Committee: Superintendent (shop); master mechanic (mechanical work); labor boss (labor work); foreman of department affected (individual department); and efficiency engineer (betterment work).

Operations Committee: Superintendent (shop); chief inspector (quality of product); functional supervisor (speeds and feeds, or jigs and fixtures, or foundry work, or belting, etc.); foreman of department affected (individual department); and efficiency engineer (betterment work).

Materials Committee: Purchasing agent (supply of materials); stores keeper (custody of materials); foreman of department affected (individual department); and efficiency engineer (betterment work).

Relations and Incentives Committee: Superintendent (shop); foreman of department affected (individual department); representative of workmen (labor); and efficiency engineer (betterment work).

Consult C. U. Carpenter, *Profit-Making Management in Shop and Factory* (New York, 1908), and C. E. Knoeppel, *The Practical Introduction of Efficiency Principles* (ib., 1914).

MANAGEMENT, SCIENTIFIC. See SCIENTIFIC MANAGEMENT.

MANAGUA, mȧ-nä'gwȧ. The capital of Nicaragua, in a healthful and fertile district on the south shore of Lake Managua (Map: Central America, D 4). The town has little or no importance save as capital. It has a good water supply, and trades in the coffee grown in the surrounding district. It is the seat of a United States consul. Pop., 35,000. Managua was made the capital of the country in 1855 to put an end to the rival claims of León and Granada. In 1876 it was destroyed by an inundation, but was soon rebuilt.

MANAGUA (mȧ-nä'gwȧ) **LAKE** (formerly called LAKE LEÓN). A lake in Nicaragua, Central America, situated 8 miles northwest of Lake Nicaragua, with which it communicates intermittently through the Tipitapa River (Map: Central America, D 4). Lake Managua is 40 miles long and 6 to 15 miles wide and its waters lie 30 feet above the level of Lake Nicaragua. It is believed that the latter was formerly at a higher level than now and that the two once formed a single lake. The shores of Lake Managua are remarkable for their picturesque scenery, which is dominated on the northwest shore by the volcano of Monotombo. Several steamers ply on the lake, and Managua, the capital of the republic, is situated on its southern shore.

MANAHIKI (mä'nȧ-hē'kê) **ISLAND.** An atoll, one of many small coral islands scattered over central Polynesia between lat. 4° and 12° S. and long. 150° and 166° W., northeast of the Samoan Islands. Manahiki is situated in about 10° S. lat. and 160° W. long. Its area is about 30 square miles, with the greater part of its surface covered by a broad lagoon. Pop., 1911, 444. It now belongs to Great Britain and, together with the Cook Islands, is under the administration of New Zealand.

MAN'AKIN (OF. *manequin*, Fr. *mannequin*, from MDutch *manneken*, dim. of *man*, man). The name manakin (or manikin) is applied to a large group of small tropical American birds difficult to define. In its narrowest sense the term is confined to the few species of the genus *Manacus*, which are birds with comparatively dull-colored plumage, but having the feathers of the chin elongated and puffed like a beard. In a broader way the term applies to the whole family Pipridæ, while by some writers it is extended to some of the Cotingidæ, a closely allied family. (A representative form of *Pipra* is illustrated on the Plate of COTINGAS, ETC.) In such senses, manakins are small, usually brightly colored birds with short, square tails and a short, vaulted, broad bill, the upper mandible hooked at the tip and with a notch behind the point. In some species the wings and tail are modified so as to become very ornamental, and these changes are sometimes extraordinary. The sexes are very different in color, the females generally being greenish, while the males are usually glossy black, ornamented with brilliant scarlet, yellow, or blue. In the genus *Heteropelma*, however, both sexes are dull-colored, while in *Machæropterus* the general color is bright green with a fiery red crown and the lower surface streaked, brown and white. The latter genus is further remarkable for the peculiar thickening of the tips of the shafts of some of the inner wing feathers, so that they appear as if ending in a pointed claw. In habits the manakins resemble tits and chickadees, hopping about in the lower undergrowth and feeding chiefly on insects. They are not song birds, however, but are more nearly related to the North American flycatchers. They are often seen on the ground, and some species nest there. A Brazilian species (*Chiroxiphia caudata*) is known as dansador on account of a peculiar habit when several are together of holding small dancing parties; one individual whistles steadily while the others dance around him, until the musician tires, when he exchanges places with one of the dancers.

MAN AND SUPERMAN. A drama by George Bernard Shaw (1903), produced in London in 1905. The leading idea is that woman is the dominating force in developing a higher form of being, the superman.

MANAOAG, mȧ-nä'wȧg. A town and junction point of Luzon, Philippines, in the Province of Pangasinán, 18 miles east of Lingayén (Map: Luzon, D 2). It has good road connection with stations on the Manila-Dagupán Railroad. Pop., 1903, 16,793.

MANAOS, mȧ-nä'ôsh. Capital of the State of Amazonas, Brazil, situated on the east bank of the Rio Negro, 10 miles from its junction with the Amazon and 1000 miles from the Atlantic (Map: Brazil, F 4). It is a large and well-built city, lighted by electricity, and has fine parks and public buildings, a lyceum, a school of chemistry, a museum, and a public library. The city has a good harbor to which ocean steamers ascend directly from Europe and the United States, and is an important commercial and shipping centre with a flourishing trade in the products of the Amazon forests, especially rubber, which it exports in large quantities. The city is connected by cable with Pará, and is the seat of a United States consular agent.

Pop. (est.), 1901, 30,000; 1912, 50,000. Manaos originated in a Portuguese fort built here in 1804 as an outpost for the slave trade. It was first called Barra do Rio Negro, and received its present name in 1836, from a neighboring tribe of Indians. It became the capital of the state in 1852.

MANAR, må-när′, Gulf of. The southern and wider part of the channel separating Ceylon from the south extremity of India (Map: India, D 8). It is nearly 150 miles wide at its broadest part, and narrows northward into Palk Strait, from which it is divided by a chain of islands and a low reef called Adam's Bridge.

MANASAROWAR, må-nä′sä-rô-wär′. Two lakes situated north of the Himalaya Mountains, one of which is the source of the Indus. According to the account in the Hindu Scriptures the eastern lake was formed when the ocean first fell down from the heavens, and it is one of the most sacred places of pilgrimage, both for the Hindus and for the Tatars.

MANAS′SAS. A town and the county seat of Prince William Co., Va., 33 miles by rail west of Washington, D. C., on the Southern and the Chesapeake and Ohio railroads (Map: Virginia, G 3). It is the seat of Eastern College and of the Manassas Industrial School, while in the vicinity lies the battlefield of Bull Run (q.v.). The town owns its water works, electric-light plant, and sewer system. Pop., 1910, 1217.

MANAS′SAS, First and Second Battles of. See Bull Run, First and Second Battles of.

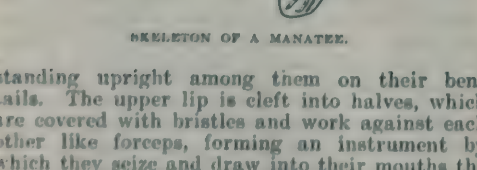
MANAS′SEH (Heb. *Mĕnashsheh,* of uncertain etymology). According to Gen. xli. 51, the eldest son of Joseph and eponymous ancestor of the tribe of Manasseh. Manasseh and Ephraim are regarded by modern scholars as representing two offshoots of a Joseph tribe, the parent branch of which (see Joseph) apparently disappeared in Goshen (q.v.), the territory adjoining Egypt on the northeast and counted as belonging to it. Of the two, Manasseh was the first to cut loose, and was therefore represented in tradition as the older; but the far more prominent part played in the history of the northern kingdom by Ephraim is reflected in the forty-eighth chapter of Genesis, where Jacob, in blessing the two, intentionally mentions Ephraim first, although the younger. Both Manasseh and Ephraim are represented as born in Egypt and sons of Joseph's Egyptian wife. If the tradition rests upon a genuine reminiscence, it may be taken as an indication that the extension of the Joseph tribe into several branches took place in Goshen. Manasseh and Ephraim appear as the most prominent of the tribes that formed the Kingdom of Israel. The territory occupied by Manasseh on the west of the Jordan lay to the north of Ephraim and reached westward to the sea, including the plain of Sharon (Josh. xvii), but the tribe continued to grow and a branch settled to the east of Jordan, occupying part of Gilead, the rich pasture lands of Bashan and the country extending northward from a point above the river Jabbok to Mount Hermon (Josh. xiii. 29–31). The heroes Gideon and Jephthah (Judg. vi. 15, xi. 1) belonged to Manasseh, but, after the formation of the kingdom, Ephraim entirely eclipses Manasseh, of which we hear again only at the time of the invasion of Tiglath-pileser IV (734 b.c.), who carried off the eastern division of the tribe to Assyria (1 Chron. v. 26). The tribe also suffered severely during the various wars with Damascus (2 Kings x. 32–33; cf. Amos i. 3).

MANASSEH. King of Judah, son of Hezekiah and father of Amon. He began to reign c.686 b.c., at the age of 12. His reign is said to have extended over 55 years (2 Kings xxi. 1; 2 Chron. xxxiii. 1), but this figure may be somewhat too high, as his death appears to have taken place no later than 639 b.c. Of the events during his long reign we know little. The narrator in Kings, being so largely interested in the religious side of history, contents himself merely with references to religious conditions in the days of Manasseh. The religious reforms introduced by Hezekiah, tending towards a purer Yahwe worship freed from the Canaanitish practices, naturally aroused opposition, and during Hezekiah's lifetime symptoms of a reaction already began to manifest themselves. The death of Hezekiah marked the height of the reaction, and Manasseh favored the old system and went even to greater lengths than his predecessors in blending the Yahwe cult with foreign elements. Besides readoption of the old Canaanitish practices, Babylonian and Assyrian customs were introduced (2 Kings, xxi. 5–7), and for this the King naturally incurred the hatred of the later historians, who purposely ignored other events of his reign. It appears on the whole to have been peaceable and prosperous, but Manasseh was obliged to pay tribute to Assyria. The story told in Chronicles (2 Chron. xxxiii) of Manasseh's capture by the Assyrians, and of his humbling himself before God and his acts of repentance, is thought to be fictitious. The Book of Kings does not say a word about it, and it resembles a Midrashic tale to illustrate the punishment merited by a king who, to the author of Chronicles, appeared the embodiment of wickedness. The later Jewish Haggada added to such stories of Manasseh's wickedness and subsequent conversion. Consult Rudolf Kittel, *Geschichte des Volkes Israel,* vol. ii (2d ed., Gotha, 1909), and Julius Wellhausen, *Israelitische und jüdische Geschichte* (7th ed., Berlin, 1914).

MANASSEH BEN ISRAEL (1604–57). A Hebrew scholar and cabalist. He was born at Lisbon and educated at Amsterdam, where his father had removed to escape persecution. At the age of 18 he took the place of his former instructor, Rabbi Isaac Uzziel, in the Amsterdam synagogue. In 1626 he set up a Hebrew printing press at Amsterdam and in 1632 published the first volume of his *Conciliador,* a learned harmony of the Pentateuch. Its author was recognized as a great Hebrew scholar, and among his correspondents were Vossius, Grotius, and Huet. In 1656 Manasseh went to England to obtain permission from Parliament for the reëstablishment of the Jews in England, banished from that country since the time of Edward I (1290). Parliament refused to pass the measure, but Cromwell favored it and unofficially permitted a large number of Jews to settle in London. Manasseh died at Middelburg on his way home. His wide learning, the services he rendered his people, the renown he enjoyed among men not of his race, his piety and amiability, have made him a venerated figure in Jewish history. Besides the *Consiliador,* he published editions of the Talmud and Bible in Hebrew; also *Esperanza de Israel* (1650); *Pedro Glorioso* (1655); *Vindiciæ Judæorum,* which appeared at London in 1656 during his stay in England.

MANAS′SES, Prayer of. An apocryphal fragment, not forming a part of the Hebrew canon nor of the deuterocanonical books, but found among the canticles appended to the psalter in Codex Alexandrinus and some other majuscules and cursives, as well as in the *Didascalia*, incorporated into the Apostolic Constitutions, in connection with a quotation of 2 Chron. xxxiii. 12 f. There are Latin, Syriac, Armenian, Slavonic, and Ethiopic versions. It is a psalm expressing the infinite compassion of God and the efficacy of true repentance, as shown in the case of the greatest sinner. Most scholars think that it was written originally in Greek, and the attempts to prove a Semitic original have not yet been convincing. It is apparently later than the Greek translation of Chronicles and earlier than the *Didascalia* (c. 200 A.D.). Consult Ryssel, in E. F. Kautzsch, *Apokryphen und Pseudepigraphen* (Halle, 1899), and H. E. Ryle, in R. H. Charles, *Apocrypha and Pseudepigrapha of the Old Testament* (Oxford, 1913).

MAN′ATEE′ (Sp. *manatí*, from Haitian *manati*, big beaver). An American sea cow of the genus *Manatus*, now nearly extinct on the coast of the United States, but still to be found in the West Indies, eastern Central America, and tropical South America. Manatees are large, seal-like animals, sometimes 10 feet long and weighing more than a ton, with rounded, fleshy tail fins, no hind legs, and the fore legs modified into swimming paws, the bones within which are of the normal type, and which have small, flat nails, except in the Orinoco species. The skin is very thick, dark gray, finely wrinkled, and sparsely provided with stout hairs, most numerous about the head and muzzle and on the palmar surface of the flippers. These animals are entirely aquatic and spend their lives in estuaries, lagoons, and rivers, rarely going out into salt water. They ascend the Amazon and Orinoco almost to their sources, and are incessantly hunted by the natives for their veal-like flesh and the oil which may be obtained from the layer of blubber beneath the skin. They are good but by no means active swimmers, are sluggish in their movements, and spend most of their time in weedy places, where they browse on the aquatic plants, often by standing upright among them on their bent tails. The upper lip is cleft into halves, which are covered with bristles and work against each other like forceps, forming an instrument by which they seize and draw into their mouths the leaves and grasses that form their fare. Connected with this food and manner of feeding is a remarkable dental feature, viz., the large number of molar teeth. These seem indefinitely to increase during the animal's life, and it is suggested that they are worn away by the character of the food—chiefly algæ mixed with much sand. Only one young one is produced annually, but this is nursed and guarded by the mother with extreme care. The young apparently are entirely defenseless, but have few enemies to menace them after they get their growth. Manatees have frequently been kept alive in aquariums for a few months and have proved gentle and docile. Once they were plentiful along both coasts of Florida, but their helplessness led to their destruction, until at the close of the nineteenth century none were left but a small, protected herd in the Miami River. Whether the Florida form, called *Manatus* (or *Hydrodamalis*) *latirostris*, is really distinct from the widely distributed *Manatus americanus* is undecided. The animal of the Orinoco is certainly a separate species (*Manatus inunguis*), distinguished by lack of finger nails. See Sea Cow; and cf. Dugong. Consult C. H. Townsend, "Notes on the Manatee," in *New York Zoölogical Society, Eighth Annual Report* (New York, 1904).



SKELETON OF A MANATEE.

MANATT, J(ames) Irving (1845–1915). An American Greek scholar. Born at Millersburg, Ohio, he served as a private in the forty-sixth Iowa Infantry in 1864; graduated from Iowa (now Grinnell) College in 1869 and from Yale University (Ph.D.) in 1873; and studied at the University of Leipzig in 1876–77. He served as professor of Greek at Denison University (1874–76) and at Marietta College (1877–84) and as chancellor of the University of Nebraska (1884–89). He was United States Consul at Athens in 1889–93, and from 1892 to his death was professor of Greek literature and history at Brown University. He edited Xenophon's *Hellenica*, with commentary (1888), and is author of *The Mycenæan Age* (1897), with Dr. Tsountas, and *Ægean Days* (1913).

MANAUNG. See Cheduba.

MAN′BY, George William (1765–1854). An English inventor of life-saving apparatus, born in Suffolk. He served seven years in the militia and in 1803 was appointed barrack master at Yarmouth. In 1807 he began working on his life-saving apparatus, by which in 1808 he saved the crew of the stranded brig *Elizabeth*. He twice received grants of money from Parliament, to which were added honorary distinctions from many foreign governments. It was estimated that by the time of his death nearly 1000 persons had been rescued from stranded ships by means of his apparatus. His publications include *An Essay on the Preservation of Shipwrecked Persons, with a Descriptive Account of the Apparatus* (1812). Consult the sketch by Aleck Abrahams in *Notes and Queries*, series 10, vol. i (London, 1904).

MANCAN′DO (It., failing). A term in music denoting a gradual decrease in loudness.

MANCE, mäns, Jeanne (1606–73). A French philanthropist, born at Nogent-le-Roi. Her religious feeling was intense and she early vowed perpetual chastity, though she felt no inclination to become a nun. Influenced by the story of Madame de la Peltrie, she blindly determined to go to Canada and in 1641 went to La Rochelle to embark. While there she met Dauversière, who was founding a religious community to maintain a hospital at Montreal in honor of St. Joseph, and determined to go with Maisonneuve (q.v.) and his men. Three other women at the last moment joined the expedition, which spent the first winter at Quebec, going to Montreal in 1642. The hospital was built with funds furnished by Madame de Bullion, and Madamoiselle Mance was in charge. She became second only to Maisonneuve in importance to the colony, as many executive details fell to her, in addition to her care of the sick and her work for the conversion of the Indians. She made several trips to France to secure aid in the work and stimulate the flagging zeal of the Associates of Montreal. She was also influential in bringing about the cession of the island to the Sulpicians, when the Associates were about to disband in 1657 (though the cession did not take effect for several years), and served as head of the Sisters of St. Joseph until her death. Consult Faillon, *Vie de Mlle. Mance et histoire de l'Hôtel Dieu de Villemarie dans l'île de Montreal en Canada* (Villemarie, 1854).

MANCH, mänsh, or **MAUNCH** (OF., Fr. *manche*, sleeve, from Lat. *manicæ*, sleeve, handcuff, from *manus*, hand). A frequent charge in English heraldry, meant to represent a sleeve with long pendent ends, of the form worn by ladies in the reign of Henry I. See HERALDRY.

MANCHA, män′chȧ, LA. A district of Spain, in the provinces of Ciudad Real and Albacete, forming the southernmost part of the Kingdom of New Castile (Map: Spain, D 3). It is a level, arid, and treeless plateau, nearly 2000 feet above sea level, and for the most part covered with esparto grass, which is an article of export. The upper waters of the Guadiana run through the territory with a sluggish flow. In spite of the dryness of the region, it produces considerable quantities of wine and grain. It is celebrated in Cervantes' novel *Don Quixote de la Mancha*.

MANCHE, mäɴsh, LA. A maritime department in the northwest of France, part of the old Province of Normandy (Map: France, N., D 3). Area, 2476 square miles. Pop., 1901, 491,372; 1911, 476,119. It derives its name—signifying sleeve—from the configuration of the English Channel (Fr. *La Manche*), which borders its shores on three sides. It has a shore line of 200 miles, the chief harbor being Cherbourg. The surface of the department is irregular, being traversed from north to south by the Cotentin Hills. The Vire, the Douve, and the Selune are the chief rivers. Flax, hemp, and fruit are extensively cultivated, and apples are grown. Horses of the famous Norman breed and excellent cattle and sheep are raised. Capital, Saint-Lô. See Plate of MONT ST. MICHEL.

MANCHESTER, măn′chĕs-tẽr. A county borough and city geographically in southeastern Lancashire, England, on the small rivers Irwell, Medlock, and Irk, 31 miles east-northeast of Liverpool and 188 miles north-northwest of London by rail (Map: England, D 3). It is practically contiguous, on the west, with Salford, itself a county borough, from which it is separated only by the Irwell. Manchester is an inland port, on the Manchester Ship Canal, and the great centre of cotton manufacture. The city is irregularly built, with Market Street, extending southeast from the Irwell, as its central thoroughfare. The central part of the city is given over to business; the east side is characterized by workshops and factories; the south side is a distinctively residential district, which in its outer portions becomes semirural. Manchester exhibits almost every urban aspect, from the attractiveness of the outlying lawns and gardens to the squalor and congestion of the slums. The principal public buildings include the immense town hall (1877), in a form of Gothic, having a main tower 286 feet high and built at a cost of more than a million pounds sterling; the Royal Infirmary, which was founded in 1752 and whose new building was opened in 1909; the Royal Exchange (1869), in the Italian style, whose meeting hall is one of the largest in England; the Royal Institution (Corporation Art Gallery), in Doric style; the Free Trade Hall, in Lombardo-Venetian style, which will seat 5000 persons; the Assize Courts (1864), in an early English and Decorated composite; the Memorial Hall; the Athenæum; and the Doric branch Bank of England. Many of the mercantile establishments are splendid structures. Among the ecclesiastical buildings are the cathedral, commonly called "the Old Church," a good example of the Perpendicular style, though built (in the early part of the fifteenth century) as a parish church (it was restored in the nineteenth century, and the tower virtually rebuilt); and the Roman Catholic (Jesuit) church of the Holy Name, a modern Gothic structure notable for its costly decoration. There are many other churches, the nonconformist far outnumbering the Anglican. Of numerous public monuments the most notable are a Prince Albert memorial in Albert Square, a bronze statue of Richard Cobden in St. Ann's Square, one of Cromwell (unveiled in 1875) at the foot of Victoria Street, and statues of Queen Victoria, Watt, Dalton, and Peel in Piccadilly.

Manchester is encircled by populous suburban municipalities, connected by rail and tramways; numerous bridges connect it with Salford. Both boroughs were enfranchised by the Reform Bill of 1832, Manchester returning two members and Salford one member to Parliament. The redistribution of seats in 1885 gave Manchester six members and Salford three. Manchester was incorporated as a municipal borough in 1838 and Salford in 1844. Manchester was made a bishopric in 1847, received the title of city in 1853, and became a county borough in 1889. In 1885, in 1890, in 1894, in 1901, in 1903, in 1904, and in 1909 the municipal boundaries were enlarged and the suburbs of Bradford, Rusholme, Blackley, Moston, Newton Heath, Openshaw, Gorton, Prestwich, Moss Side, Withington, Levenshulme, etc., were included within the city limits. For purposes of administration, Manchester is divided into 34 wards and is governed by a city council and board of aldermen; the mayor, who received the title of lord mayor in 1893, is elected by the council and receives no salary. The council elects from its own members standing committees which supervise the various municipal departments. Manchester derives from its city rates more than enough for its municipal needs, taken together with the profitable undertakings which the city owns. Until 1847 the water supply was controlled by a private company and was so unsatisfactory that the city took it over. Large sums were expended during the next 28 years in enlarging the plant. In 1874 Parliament passed a bill authorizing the city to get a new supply from Thirlmere, a lake 96 miles distant at the foot of Helvellyn on the southeast border of Cumberland, which was subsequently acquired by the city. The works, from 1848 to their completion in 1884, cost £3,148,000. The daily consumption is over 38,000,000 gallons. Manchester possesses the oldest municipal gas works in the world, its ownership dating from 1807. The city supplies with gas several of the adjoining towns and derives a considerable annual profit from the works. Its electric-light plant, opened in 1893, is also a successful municipal enterprise. Manchester owns its street railways, but does not operate them, leaving that to a private company in consideration of a rental equal to more than 10 per cent upon the city's investment. The city exercises a strict supervision over all the details of the company's work.

Manchester owes its growth and prosperity very considerably to its water communication with the sea. In 1721 a plan was made by Thomas Steers, and subsequently carried out, for extending over the Irwell, by means of locks and weirs from Warrington to Manchester, the barge navigation which existed between Liverpool and Warrington. In 1761 a canal, built by James Brindley for the Duke of Bridgewater (1736–1803) from the duke's collieries at Worsley to Manchester, was opened to traffic. This canal was carried in an aqueduct over the Irwell at Barton and was the first canal in England which throughout its course was independent of a natural stream. In 1772, the Duke and Brindley completed a canal from Manchester to the Mersey at Runcorn which opened competition with the Irwell-Mersey navigation to Liverpool. Both routes accommodated barges of 50 tons. The Manchester-Runcorn canal was about 28 miles in length, nearly three times as long as the Worsley-Manchester. Although to these facilities for trade was subsequently added the Liverpool and Manchester Railway, the need of a ship canal ultimately asserted itself. Plans were submitted in 1825 and 1840, but the movement for a ship canal which was finally successful did not begin until 1882. The undertaking, opposed by Liverpool and the railway, received parliamentary sanction in 1885, and work began in November, 1887. The Manchester Ship Canal was opened to traffic in January, 1894; the official opening ceremony took place May 21, 1894, when Queen Victoria visited Manchester. The canal is 35½ miles long. It begins at Eastham, on the Cheshire side of the Mersey estuary, about 6 miles above Liverpool, and passes in or near the estuary to Runcorn, 12¾ miles; thence to Latchford, a part of Warrington, in Lancashire, it is inland, 8¼ miles; from Latchford, where are the first locks, the canal continues to Manchester, 14½ miles. The minimum bottom width of the canal is 120 feet; the minimum depth 28 feet (originally 26 feet). Both sides are faced with heavy coursed stone. The total excavation, including docks and subsidiary work, was more than 54,000,000 cubic yards, of which nearly one-fourth was sandstone rock. The expenditure to 1900 on the works, including equipment, was £10,328,000; the purchase of the old canal navigations, interest, other expenses, etc., increased the total outlay to £15,248,000. At Barton the ship canal crosses, on a lower level, the aqueduct of the Bridgewater Canal. The passage of ships was made possible by introducing into the Bridgewater Canal a swing aqueduct. The fixed aqueduct is the first navigable aqueduct in England, and the swing aqueduct the first of its kind in the world. The movable portion of the swing aqueduct, including the water, weighs 1600 tons. The ship canal has enormously increased Manchester's industrial and commercial activity. The traffic of toll-paying merchandise has steadily increased. In 1894 this amounted to 925,659; in 1900, 2,784,843; in 1910, 4,618,070; and in 1913, 5,457,218 tons. The receipts for these years amounted to £97,901, £290,830, £555,735, and £654,937 respectively. Manchester has 6 miles of quayage and dock accommodations of 100 acres. To make its provisions for all the commercial and industrial facilities complete, the city takes considerable pains to keep up a good supply of efficient and highly skilled craftsmen, mechanics, foremen, etc., for its diverse industries. All the chief technical schools, formerly conducted by private individuals, have been consolidated under a municipal management. Manchester has many educational institutions. The oldest of these is the grammar school founded by Hugh Oldham (died 1519), who was Bishop of Exeter and a noted benefactor of Corpus Christi College, Oxford. The conveyances of the property which constitutes the endowment of the school bear date of 1515 and 1525. The school has 250 free scholars and others paying fees. The second-oldest institution is the Chetham Hospital and Library, a boys' school whose foundation was provided by will of Humphrey Chetham (1580–1653), a merchant, woolen manufacturer, and money changer of Manchester. There are also another grammar school, endowed by William Hulme (1631–91), the Nichols Hospital (1881) for the education of orphan boys, and three high schools for girls. The municipality provides many elementary schools, a school of art, a school of technology, a teachers' college, various special schools, etc. In 1846 John Owens (born 1790), a Manchester merchant, left the residue (£96,655) of his personal estate to found a boys' college for secular instruction. (See MANCHESTER, UNIVERSITY OF.) There are several denominational colleges in Manchester. Manchester was among the first towns in England to adopt the Free Libraries Act, which allows an appropriation of a penny in the pound on the local assessment for parks, libraries, and museums; and here also was established the first free lending library in England. Numerous branch lending libraries and a museum have since been established in Manchester, and several branch lending libraries and an excellent museum in Salford.

The parks of Manchester are 39 in number, covering an area of 1103 acres. The chief are Heaton Park, 692 acres; Boggart Hole Clough, 76 acres; and Queens, Philips, Alexandra, Peel, and Whitworth parks. Like Glasgow, it has a large precipitation and filtration plant for the utilization of its sewage (for description of plant, see GLASGOW) and for the prevention of pollution of its river. The fertilizers thus obtained bring a good price. The garbage is burned up in the furnaces, and the noncombustible part is used to fill in outlying low ground belonging to the city, which is thus converting it into good building land, which sells at an advanced price. There are municipal bathing establishments, markets, abattoirs, and workmen's dwellings. The city lets several hundred dwellings in tenements, as well as private cottages, to workmen's families, the rents being $2.50 per room per month, and about $5 per month for a four-room cottage. The death rate in Manchester is quite high, being, according to the statistics for 1911, 26 per 1000 of population, or much higher than in London or Glasgow. As an industrial centre, it is one of the oldest, as well as one of the most important, in England. The chief industry is cotton spinning, weaving, and manufacturing, including calico printing, bleaching, and dyeing; there are also considerable manufactures of silk and mixed goods, of small wares, of machinery and tools, of paper and chemicals. Manchester is a depot for all kinds of textile fabrics. In the foreign and colonial trade tonnage entered at Manchester (including Runcorn) in 1902 was 1,002,336, and cleared 713,172; in 1907, 1,363,859 and 1,161,115; in 1912, 1,335,415 and 1,079,736. The imports of Manchester (including Runcorn) were valued at £17,620,772 in 1902, and the exports £8,310,436 (of which £8,001,563 domestic); in 1907, £30,402,229 and £16,826,627 (£15,754,398); in 1912, £35,111,128 and £21,606,841 (£21,182,625). Manchester is the seat of an American consul.

The population of Manchester increased rapidly during the nineteenth century. Starting with a population of 75,000 in 1801, it grew to 126,000 in 1821, 303,000 in 1851, 644,873 in 1901, and 714,333 in 1911. The area of the city at the 1911 census was 21,645 acres. The adjoining county borough of Salford, with an area of 5202 acres, had in 1901 a population of 220,957 and in 1911 231,357. Thus, the combined population of the two boroughs was 865,830 and in 1911, 945,690. The suburban population is enormous.

Roman remains have been found in great numbers at Manchester, but the history of the place can be traced only to Anglo-Saxon times, the name Mamcester, or Mameceaster, appearing in the *Anglo-Saxon Chronicle* in 923. The town suffered much from the Danes, but prospered nevertheless. In the thirteenth century fulling mills were at work there. In 1301 Manchester became a free borough with a considerable degree of self-government. It thrived especially after the fourteenth century, and about 1650 was a busy town, with nearly 6000 inhabitants. During the Civil War it was held successfully for the Parliament, but in the eighteenth century it became strongly Jacobite and participated in the rebellions of 1715 and 1745. In the early part of the nineteenth century Manchester was prominent in the liberal and reform agitation, and was the scene, in 1819, of the so-called Peterloo Massacre (q.v.). After 1832 it was the headquarters of the free-trade movement, and gave its name to the famous Manchester School of Economy.

MANCHESTER. A town in Hartford Co., Conn., 9 miles east of Hartford, on the Hockanum River and on the New York, New Haven, and Hartford and the South Manchester railroads (Map: Connecticut, F 2). It was taken from East Hartford and incorporated in 1823, and includes the villages of Manchester, South Manchester, Buckland, Manchester Green, and Highland Park. The town has the great Cheney silk mills, employing 4500 persons, paper mills, cotton and woolen mills, and manufactories of electrical appliances, soap specialties, machinery, needles, and tinware. There are public libraries in the villages of Manchester and South Manchester. First incorporated in 1823, Manchester was reincorporated in 1907, and has adopted a modified commission form of government by which seven selectmen act as a board of supervisors. Pop., 1900, 10,601; 1910, 13,641; 1914 (U. S. est.), 14,935; 1920, 18,370.

MANCHESTER. A city and the county seat of Delaware Co., Iowa, 47 miles west of Dubuque, on the Maquoketa River and on the Illinois Central and the Manchester and Oneida railroads (Map: Iowa, F 2). It has a Carnegie library and, in the suburbs, a United States fish hatchery. The city is the commercial centre of the adjacent farming, stock-raising, and dairying country, and manufactures flour, brick and tile, etc. The industrial interests are promoted by good water power. Manchester owns its water works. Pop., 1900, 2887; 1910, 2758.

MANCHESTER. A town including several villages in Essex Co., Mass., 9 miles northeast of Salem, on Massachusetts Bay and on the Boston and Maine Railroad (Map: Massachusetts, F 2). It is a popular summer resort, one of the leading attractions being a "singing beach." It has a public library in the Coolidge Memorial Library Building, and manufactories of furniture. The town owns and operates its water works and sewer plant. Pop., 1900, 2522; 1910, 2673.

Manchester was settled probably as early as 1630, and was known as "Jeffry's Creek" until 1645, when it was incorporated as a village under its present name. It first became a summer resort about 1845, when Richard H. Dana built a summer cottage here. Consult Lamson, *History of the Town of Manchester, 1645–1895* (Manchester, 1895).

MANCHESTER. The largest city of New Hampshire, and one of the county seats of Hillsboro County, 18 miles by rail south-southeast of the State capital, Concord, and 56 miles by rail north-northwest of Boston, Mass., on the Merrimac River, at its confluence with the Piscataquog, and on the Boston and Maine Railroad (Map: New Hampshire, G 8). It extends along both banks of the two rivers. An immense amount of water power for manufacturing is derived from the Amoskeag Falls (about 55 feet) of the Merrimac by means of a carefully projected system of canals, though steam is used also in a number of the mills. The most extensive industries are cotton and woolen cloth manufacturing. In 1915 there were 36 mills with a combined annual output of 246,000,000 yards of cotton and 2,000,000 yards of woolen cloth. They employed about 15,000 hands and their total output had a value of $35,000,000. Manchester is also noted for the production of boots and shoes; about 7500 persons are employed in this industry. There are also paper and woolen mills, fire-engine and locomotive works, needle and knitting-machine factories, hosiery and underwear factories, carriage and wagon works, tanneries, and manufactories of cigars, brushes, beer, lumber products, furniture, etc. The combined industries of the city, which employ about 25,000 persons, represent a capital of nearly $26,000,000 and have an output valued at $46,000,000.

The city is well laid out with fine, broad streets, and has a handsome United States government building, county courthouse, State industrial school, Roman Catholic cathedral, a large public library, and 15 public parks, in all embracing 200 acres. Other noteworthy features are the Notre Dame, Sacred Heart, and Elliott hospitals, Women's Aid Home, Weston Observatory, Holy Angels' Convent, and the Gale, Masonic, and Children's homes. Manchester's income in 1912–13 was $2,268,000, while its payments amounted to $2,392,000, the chief items of expenditure being $202,000 for education, $139,000 for the fire department, $84,000 for sanitation, $77,000 for the police department, and $58,000 for the water works, which are owned and operated by the city, having been built in 1873 at a cost of over $1,500,000. Pop., 1870, 23,536; 1880, 32,630; 1890, 44,126; 1900, 56,987; 1910, 70,063, including 29,692 persons of foreign birth and 36 negroes; 1914 (U. S. est.), 75,635; 1920, 78,384.

MANCHESTER. A town and one of the county seats of Bennington Co., Vt., 53 miles by rail northeast of Troy, N. Y., on the Battenkill River and on the Rutland Railroad (Map: Vermont, B 7). It is a popular summer resort, situated amid fine mountain scenery, at the base of Mount Equinox (3847 feet above sea level), which commands a superb view, and has the Skinner Memorial Library and the Burr and Burton Seminary. Most of the sidewalks are paved with marble. The town is surrounded by a productive farming region, and has large lumber and marble interests and manufactures of fishing rods and ginger champagne. The water of the mineral springs here is exported. Before the organization of Vermont, Manchester was for many years claimed by both New Hampshire and New York. The town was incorporated in 1761 and the village in 1900. Pop., 1900, 1955; 1910, 2044. Consult Munson, *The Early History of Manchester* (Manchester, 1876).

MANCHESTER. Formerly a city in Chesterfield Co., Va., annexed to Richmond in 1910. It has important agricultural and coal-mining interests, and there are large flouring mills, cotton mills, foundries, paper mills, tanneries, brickyards, glass, furniture, and woodenware factories, and repair shops of the Southern Railway. Good water power is afforded by the James River, which has a fall of 100 feet in less than 60 miles.

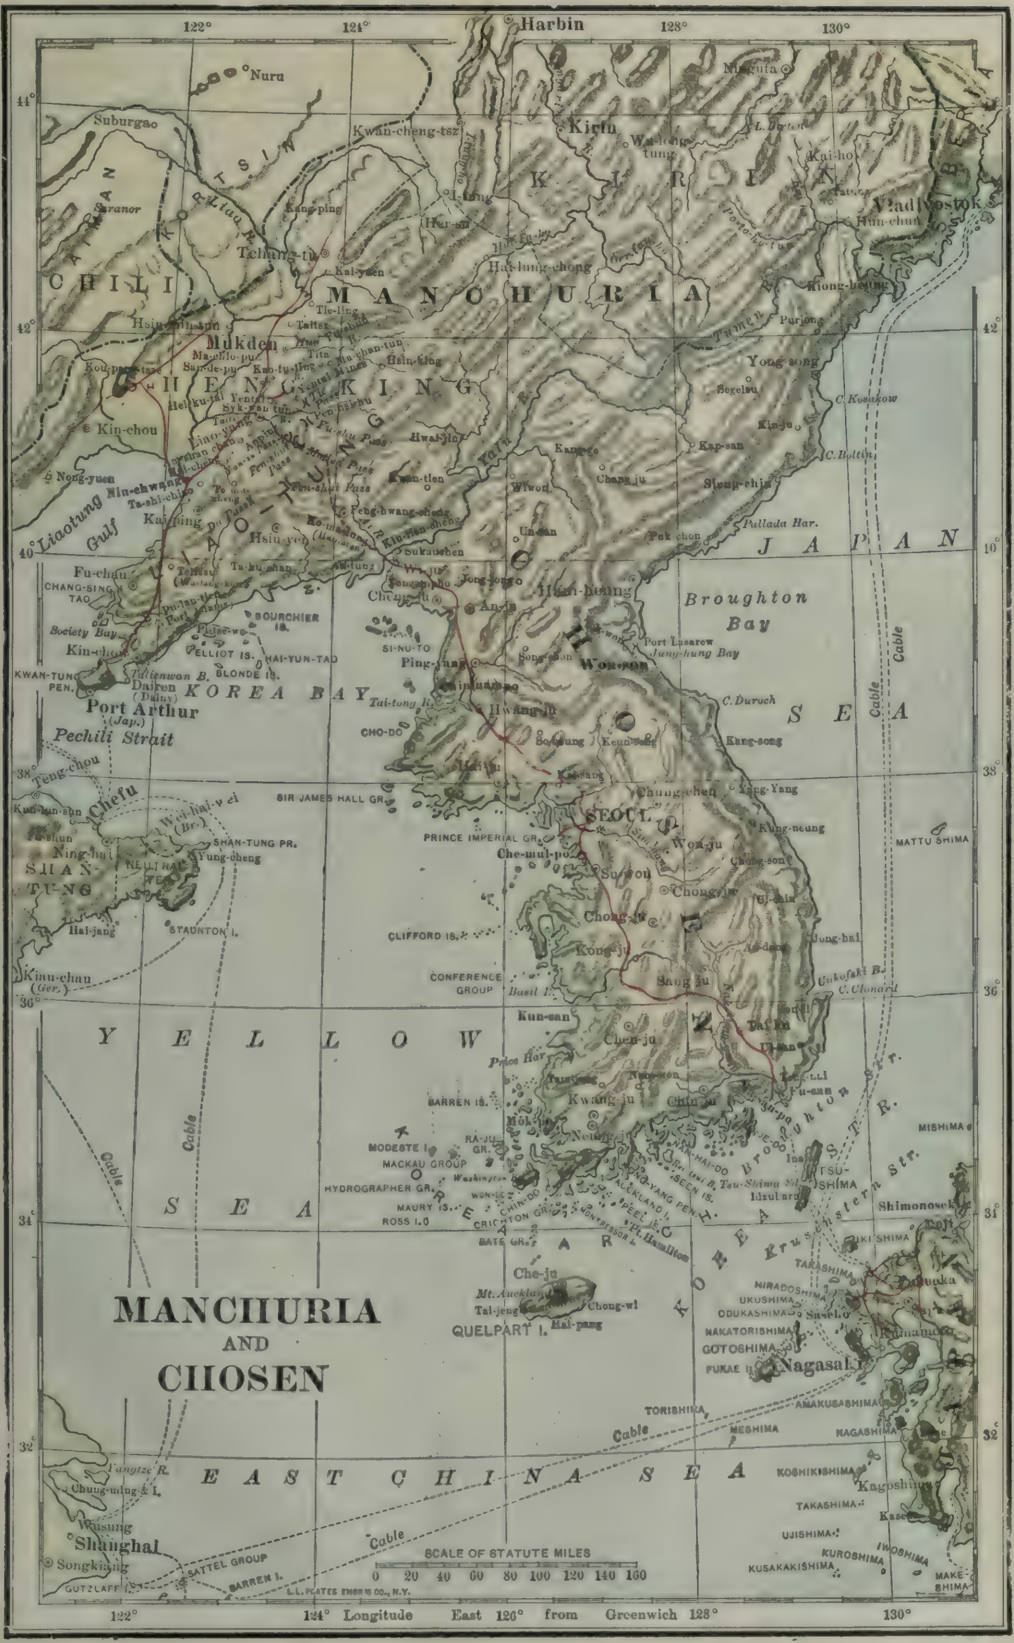
MANCHESTER, UNIVERSITY OF, Manchester, England. A university which had its origin in the foundation, by the will of John Owens, of Owens College to provide higher education without denominational restrictions. Work was begun in 1851 in a house formerly the residence of Richard Cobden (q.v.). The successful growth of the college dated from the sixties. In 1872 the college secured the incorporation of the Manchester Royal School of Medicine. At the same time the existing site became inadequate and new buildings were erected on another site, which has again outgrown the present requirements. Women were admitted to special courses of lectures in 1874, but were not fully admitted as matriculated members until 1883. In 1880 Owens College became one of the constituent members, together with what are now the universities of Leeds and Liverpool, of the Victoria University. On the dissolution of that body Owens College became in 1903 the Victoria University of Manchester. While the aim of the university is so far as possible to meet the local needs, and although it relies to a great extent on local support, it has attained an international reputation in certain fields of work. The university was one of the first in the country to establish a course and degree in commercial subjects. The university has developed strong departments not only in the sciences but also in English, history, and education, while its medical facilities have been greatly supplemented by the establishment of an excellent hospital in its vicinity. In several departments, such as music, theology, and technology, the university coöperates with several local institutions. The financial support is derived from endowments, fees, and grants from the local and central authorities. In 1913–14 there were 256 members on the faculty and 1840 students.

MANCHESTER COPPY. See CANARY.

MANCHESTER SCHOOL OF POLITICAL ECONOMY. The name applied to a group of English economic writers under the leadership of Richard Cobden and John Bright, who advocated principles of free trade and *laissez faire*. In 1820 the merchants of Manchester became prominent as defenders of free trade, and in 1838 the Chamber of Commerce of Manchester issued a vigorous denunciation of the protective principle. The immediate object of attack was the Corn Law; and the Anti-Corn Law League, organized in 1839 by the Manchester free traders, carried on an educational campaign which drew the attention of the whole world. The term Manchester school has come to be applied as a term of reproach by writers of the German historical school of economics and by practical protectionists. It must be admitted that writers of the Manchester school often manifest a tendency to limit unduly the field of governmental activity and to overrate the beneficence of unrestricted competition. See the articles FREE TRADE; CORN LAWS.

MAN'CHINEEL' (Fr. *mancenille, manzanille*, from Spanish *manzanillo*, manchineel, dim. of *manzana*, apple, probably from Lat. *matiana* (*mala*), *matian* (apples), nom. pl. of *Matianus*, relating to Matius, from *Matius*, name of a Roman gens), *Hippomane mancinella*. A tropical American tree of the family Euphorbiaceæ. Its acrid milky juice is reputed very poisonous. The tropical American Indians poison their arrows with it. Its perfumed fruit is so acrid as to be inedible.

MANCHURIA, man-cho͞o'rē-ȧ (the land of the Manchus). The northeastern part of the Chinese Republic, situated east of Mongolia and the Argun River (which formerly traversed Manchurian territory), south of the Amur River (which separates it from Siberia), and west of the Usuri, which separates it from Primorsk (Maritime Province) or Russian Manchuria (a Chinese possession until 1860). It is bounded on the southeast and south by Chosen (Korea), the Bay of Korea, and the Gulf of Liaotung, and is included between the parallels of 39° and 53° 30′ N. and the meridians of 117° and 135° E. As already indicated, it was formerly much more extensive than it is now, Russian encroachments (beginning about the middle of the seventeenth century) having gradually narrowed it down to its present officially



MANCHURIA
AND
CHOSEN

estimated area of 363,600 square miles. The country is known to the Chinese as Tung San Sŭng (or Shêng), i.e., the Three Eastern Provinces, referring to its three administrative divisions: (1) the Province of Tsitsihar or Heilungkiang in the north, with an estimated area of 202,000 square miles; (2) Kirin (q.v.) in the centre, the original home of the Manchus, area 105,000 square miles; and (3) Shingking or Fung-t'ien-fu in the south, area 56,000 square miles. The last one is, strictly speaking, no part of Manchuria, having been a Chinese province before the rise of the Manchus.

Topography. The whole eastern part of the country bordering on Chosen and Russian Manchuria is occupied by huge mountain masses with many fertile valleys. The general trend of the ranges is from northeast to southwest, and the backbone of the whole is the Shan-a-lin or Long White Mountains. In the northwest, within the loop formed by the Argun and the Amur, is found the main mass of the Greater Khingan (or Hingan) system, stretching southward into Mongolia, but sending out many spurs and ridges both westward towards Siberia and eastward through Tsitsihar, forming in the centre of that province the hills and plateaus of the Lesser Khingan ranges. South of this (extending as far as the Gulf of Liaotung) and west of the Shan-a-lin ranges lies the great plain of the country, diversified by hill and dale, with occcasional swampy regions, but of great agricultural value, producing large crops of pulse, barley, wheat, millet, maize, rice, cotton, indigo, tobacco, sesame, opium, ginseng, rhubarb, etc., and capable of sustaining immense herds of cattle. It has been estimated that at present only one-fifth of the arable land is under cultivation.

The mountains are still well covered with forests, especially in the northern province, but those bordering on Chosen are being rapidly denuded to supply the needs of China. Tigers, wolves, bear, deer, foxes, martens, and other fur-bearing animals abound, and hunting and trapping are important occupations.

Hydrography. The most important rivers drain northward to the Amur (q.v.). The two main drainage basins are those of the Sungari and the Usuri, both rising in the Shan-a-lin ranges. The former receives in its course the Nonni and the Hulan from the Khingan ranges, the Hurka or Mutan-ho from the Shan-a-lin, and many other streams. The Argun is navigable for 460 miles, the Sungari for 700 (not including its tributaries), and the Usuri for 250, but navigation is restricted by treaty to Russian and Chinese vessels. The south-flowing rivers are the Liao (400 miles), a continuation of the Shira-muren from Mongolia; the Ta-yang, entering the Gulf of Pechili at Takushan; and the Yalu-kiang (between Manchuria and Chosen), which falls into the Bay of Chosen.

Mineral Resources. Nothing is known regarding the geology of Manchuria, but its mineral wealth is known to be great. Gold is found in all the provinces, most abundantly in Tsitsihar. It is mined by the government along the Sungari near Sansing, as well as along the Hurka in the Province of Kirin. Silver, copper, lead, iron, and soda are worked to some extent. Coal is also found, and the Fushun coal mine, which forms part of the Japanese government's investment in the Southern Manchuria Railway Company, is believed to be one of the richest in the world. Its strata are from 100 to 120 feet deep and about 10 miles broad.

The Climate exhibits great extremes of temperature, but is healthful, and, being uninfluenced by the southwest monsoon, it is dry. The rainfall is only about 13 inches in the south. The minimum winter temperature varies from 7° F. in the north, and the summer temperature sometimes reaches 95° F. The rainy season occurs in July and August.

Transportation. There are many so-called highways, of which the most important runs from Peking to Siberia via Chinchowfu, Mukden, Kirin, Petuna, and Tsitsihar. However, in some seasons of the year, during thaw or continued rains, these roads are almost impassable. The chief movement of crops to the southern ports takes place in the winter, when the country is frozen solid. The absence of good roads and the inability of the railway lines completely to feed the huge territory make river transportation a necessity, and in open season boats and junks travel to every part of the three provinces, while in winter the rivers furnish ice ways for sledge traffic, accommodating freight and passengers.

There are (1915) three railway systems in Manchuria: (1) The Russian line, known as the Chinese Eastern Railway, a continuation of the Trans-Siberian system, runs southeast for 92 miles to Suifenho, and thence to Vladivostok. Construction on the main line was begun in 1897, and in 1901 it was opened at a cost of 350,000,000 rubles. In 1912 there were 1,660,533 passengers carried and 3,390,773 tons of freight. (2) The South Manchurian Railway, opened in 1907, was originally part of the Russian system, but was transferred to Japan by the Portsmouth Treaty of 1905. The main line runs south from Kuanchengtze (Changchun) for 439 miles to Dairen (Dalny). In 1912 it carried 3,392,039 passengers and 4,407,734 tons of freight. (3) The Peking-Mukden (Chung-Feng) Railway, of the Chinese government railways, which has a terminal at Peking, enters Manchuria at Shanhaikwan and runs north to Mukden. The road was opened in 1903. In addition to these roads and their branches, there are several railways planned, the most important of which are the Kirin-Hungchun line, a Sino-Japanese enterprise, and a private Chinese line from Harbin to Shuhiu.

By virtue of the land, mining, and other grants along their respective railways, Russia and Japan are making systematic efforts to develop Manchurian commerce, industry, and colonization. The centre of Russian activity is at Harbin (q.v.), and along the entire Eastern Chinese Railway the Russians have established numerous sugar and flour mills, tanneries, distilleries, oil mills, mines, etc. The Jalainor mines in 1913 produced 142,857 tons. Russian population in north Manchuria has increased (1913) from 45,000 to 56,000. Foreign firms in 1912 numbered 303, and increased to 1241 in 1913. Three of these firms are American. The Japanese in south Manchuria organized the South Manchurian Railway Company by Imperial ordinance of June 7, 1906. This company, which has a capital of £20,000,000, controls the steamship line between Dairen (Dalny) and Shanghai, manages Dairen harbor, supplies that port and other places with gas and electricity, and operates the great Fushun mines, the output of which in 1912 was 1,470,150 long tons. At

Yengtai the company mined 43,104 tons. The Penhsihu mines, on the Mukden-Antung Railway, are operated by a Sino-Japanese concern; output in 1912 was 160,000 tons. Here are also iron mines, and it is estimated that the three blast furnaces at the Penhsihu colliery can turn out 120,000 tons per annum. The South Manchurian Railway Company is especially active in establishing railway hotels and towns along the line, including numerous Y. M. C. A's; also in developing the resources of the railway area. These are considerable when it is remembered that Manchuria has one of the richest soils in the world. The company has £14,000,000 sterling in 5 per cent debentures on the London market, with the capital and interest guaranteed by the Imperial Japanese government.

Commerce. The trade of Manchuria for 1912, according to returns of the Chinese Maritime Customs, was $132,265,545. Of this, foreign countries received 62 per cent and Chinese ports 38 per cent. The trade of each Manchurian open port for 1912 was as follows:

OPEN PORTS	1912		
	NET IMPORTS		Exports
	Foreign goods	Native goods	
South Manchuria:			
Antung	$3,199,297	$724,081	$3,966,255
Chinwangtao	1,408,292	122,669	2,526,266
Dairen (Dalny)	20,849,176	2,628,297	21,762,258
Newchwang	17,516,471	6,943,748	19,680,509
Tatungkou	25,501	14,230	210,977
Total	$41,998,737	$10,433,025	$48,046,265
North Manchuria:			
Aigun	$497,010	$173,375	$165,409
Harbin	Reëxports exceeded imports		4,456,093
Hungchun	245,878	109,345	193,805
Lungchingtsun	252,393	....	85,832
Manchouli	8,098,658	892,530	1,399,768
Sansing	122,592	367,848	1,176,946
Suifenho	5,102,254	....	10,847,782
Total	$14,318,785	$1,543,098	$18,325,635
Grand total	$56,317,522	$11,976,123	$63,971,900

As computed in Haikwan taels, the total revenue of the Manchurian ports for 1912 was 3,875,696, a decrease from 1911 of 120.530 Haikwan taels. The exchange rate in 1912, however, was $0.716, owing to the high rate of silver exchange, whereas in 1911 it was $0.65 United States currency. Thus, when translated, revenue for 1912 was equal to $2,774,998, a gain of $177,451 over 1911. Of this revenue, import duties furnished $1,123,175 and export duties $1,457,393.

Although the Chinese revolution was not active in Manchuria, yet conditions were disturbed because 29 per cent of the import and 36 per cent of the export trade of the territory was domestic in 1911. In 1912 there was a considerable decrease in native importations. The European War of 1914 affected Manchuria through the activities of the German cruisers in Pacific waters and the siege of Tsingtau, the German concession in Shantung Province.

A comparison of South Manchurian with North Manchurian ports shows that the former received 74 per cent of foreign imports and 87 per cent of native imports in 1912 and 71 per cent of total exports. The two big ports of Manchuria are Dairen, in 1912 ranking fifth of all Chinese ports in total value of trade, and Newchwang, ranking eighth, both South Manchurian ports.

The principal foreign imports are clothing and hats, cotton goods, iron and steel manufactures, railway plant and material, kerosene (mainly American), wines and liquors, matches, tobacco, tea, and woolen goods. Native imports consist mainly of animals, boots and shoes, breadstuffs, coal, cotton goods, earthenware and pottery, matches, timber, and tobacco. Principal exports are beans and peas, bean cake, bean oil, coal, eggs, flour, seeds, skins (marmot, fox, sheep, goat, and squirrel), and timber. Exportations to Chinese ports (interprovincial) are mainly cotton yarn, American flour and kerosene, beans and bean cake, cereals, earthenware and pottery, mats, and oil.

Japan holds a large share of the trade in cotton goods, some of these articles exclusively. Japanese firms are materially aided by the use of Japanese money in south Manchuria, along the South Manchurian Railway. The Japanese also exchange a considerable amount of goods by barter. They have made a successful commercial invasion of north Manchuria, where they have established a Japanese bank. American kerosene, flour, and sewing machines find a good market in Manchuria.

The leading crops are beans, tobacco, and kaoliang. In 1912 the bean crop was 3,284,929 tons. From November, 1911, to November, 1912, a total of 351,000 tons of beans was exported via Suifenho and Vladivostok, 30,000 tons to Japan, and the remainder to Europe. At the port of Dairen in the Leased Territory (Japanese) 19,421 tons of beans and bean cake were exported to Hongkong, the Straits Settlements, and Europe, and 101,903 tons to Japan, while 61,304 tons were shipped to Chinese ports. A total of 15,857 tons of bean oil was sent from the port of Dairen to Europe, and 13,973 tons to Chinese ports. The bean cake shipped from Dairen goes almost exclusively to Japan. Tobacco is the next best money crop. It is grown in the upper Sungari valley and about 125 miles northeast of Mukden. The emporium of the tobacco trade is Kirin City, and the chief markets the three Manchurian provinces, Chili, and Shantung. In 1912 the value of the crop was estimated at $4,000,000. In 1912, 3,807,740 tons of kaoliang were raised. Kaoliang is a grain which is little exported, and is used as the chief grain food of the native Chinese population in Manchuria, and also as the principal grain food for animals. It is almost as handy a product as bamboo. The stalks are employed in the construction of houses, fences, and for use as fuel; the leaves furnish material for the manufacture of hats, baskets, and brooms. In 1912, 2,309,800 tons of millet were raised. There has lately been a large increase in the exportation of glutinous millet to Chosen and Japan, where it is used by the poorer people as a substitute for rice, which is at present high in price. There have been successful experiments of rice growing by the Japanese in south Manchuria, and rice farming is growing in importance along the South Manchurian and the Mukden-Antung railways. The 1912 crop was equal to 210,000 bushels. The rice is not transplanted, but is grown directly in the paddy during early May and harvested in late August or early September. During 1912 there was an increase of opium imports to the port of Dairen from 2973 to 7375 pounds. Importation was permitted in the Japanese Leased Territory until Jan. 1, 1916, when it was discontinued. Elsewhere in Manchuria opium is prohibited. The other important crops in 1912, estimated in tons, were: barley, 364,369; corn, 895,860; rice, 137,232; sesame seeds, 18,142; wheat, 1,105,048.

Population. Estimates of population vary from 14,900,000 to 29,400,000. Hosie places the total at 17,000,000; Little at 21,000,000; H. B. Morse at 16,000,000. The Michengpu (Chinese census) of 1910 gives the number as 14,917,000, which is probably too low. The Maritime Customs estimate for 1910 is 17,000,000, and, for 1913, 19,290,000. The population of Shengking Province (Fengtien) is estimated at 10,312,341; Kirin Province at 6,000,000; and Heilungkiang (the Amur Province) at 1,500,000. Chinese form the overwhelming proportion of the population, and the Manchus about one-tenth of the total. In the last 10 years there has been a considerable influx of Japanese and Russians, the former in the lower and the latter in the upper half of the territory. Each year there is an influx of Chinese laborers from Chili and Shantung provinces, and many of these undoubtedly remain. This immigration is mainly along the Peking-Mukden (Chinese) Railway, and also to the ports of Yingkow, Dairen, and Antung on the Chosen frontier.

Of the treaty ports, Harbin (q.v.) has an estimated population of 68,000; Newchwang (q.v.), 75,000; Antung (q.v.), 160,000; Sansing, 30,000; Dalny (q.v.), 75,000; Aigun, 60,000; Manchouli, 10,000; Tatungkow, 10,000; Hungchun, 8000; Lungchingtsun, 7000; Suifenho, 5000. Other important Manchurian towns are Tsitsihar, 60,000, a place where cattle fairs are held in September and October; Hulan, 30,000, with half a hundred oil mills; Baiansussu, 30,000, which has 18 distilleries and 30 oil mills; Kirin (q.v.), an important centre for tobacco, furs, and lumber trade; Petuna, 30,000, with rope and cotton-goods manufactures; and Kuanchengtze (Changchun), 80,000, one of the most important cities in all Manchuria, lying 80 miles west of Kirin, and the distributing point for the trade of northern Kirin and Heilungkiang provinces. Here also are found distilleries, oil mills, and tobacco industries. Mukden (q.v.) is the centre of a rich agricultural district, has a population of 250,000, and is theoretically open to foreign trade. Liaoyang, a Russian town before the Russo-Japanese war, has since been made, like Dairen, one of the centres of Japanese activities in south Manchuria. Port Arthur (q.v.) is not used by Japan for commercial purposes, but is of value as a strongly fortified naval base.

The government of Manchuria is vested in the central authority of the Chinese Republic at Peking, which is represented locally by three provincial governors, one for each of the Manchurian provinces. In finance, justice, and the ordinary governmental routine, these governors have practically unlimited powers, but foreign relations are delegated entirely to the administration at Peking. The Liaotung Peninsula (Kwantung), where Port Arthur and Dairen are situated, and which is known as the Leased Territory (area 1219 square miles, population in 1912 of 501,767, including 45,356 Japanese), is under the control of Japan until 1923, when the original Russian lease runs out and the land reverts by existing treaty agreement to China.

History. Many references are found in Chinese history to the savage tribes inhabiting this region even as early as the eleventh century B.C. In 712 we find a chieftain named *Ta*, whose tribe dwelt to the north of Chosen, receiving from the Chinese Emperor the title of Prince of Pohai. Later his descendants threw off the Chinese allegiance and established an independent kingdom with a centralized government and no fewer than five royal residences. Later still arose the Khitan, whose seat was in the valleys of the Hulan. They conquered eastern Mongolia, waged war on China, established a dynasty there known as the Liao (907), overthrew the Pohai in 926, and annexed their territory. In 1125 the Khitan were conquered by the Neu-chin or Jurchin, whose original seat was between the upper Sungari and the Hurka, and who possessed themselves of Manchuria, Mongolia, and north China, and there set up the Kin or Golden dynasty. Driven out of China in the thirteenth century by Kublai Khan, the Jurchin became broken up into a number of independent tribes which were later welded into one kingdom by Nurhachu (born 1559), whose chief seat lay in the south of the Long White Mountain about 100 miles east of Mukden, then an important Chinese city. He was the seventh in descent from the miraculously conceived Aisin Gioro Bukuli, the ancestor of the family until 1912 on the throne of China, and the first to apply to his tribesmen the epithet *Manchu*, "clear" or "pure," by which the last reigning dynasty in China is known to history—*Ta Ts'ing Ch'ao*, "the Great Pure." In 1616 Nurhachu took the title of *T'ien-Ming*, "Heaven-decreed," and in the following year declared war on China, then in possession of both Liaotung and Liaosi, defeated with immense slaughter an army of 200,000 sent against him, took Mukden in 1621, and on his capturing Liaoyang (which he made his capital) 70 cities surrendered to him. At his death in 1626 he was succeeded by his fourth son, who sent an army in 1627 into Korea (modern Chosen), which had been aiding the Chinese, conquered it and exacted tribute, and advanced into Liaosi and Mongolia. Meanwhile decay had seized the Ming dynasty then on the throne of China; formidable rebellions existed everywhere; one of the rebel leaders had captured Peking, and the Emperor stabbed himself and his daughter. Wu San-kwei, the general operating against the Manchus in Liaosi, at once patched up a peace with them and invoked their assistance in restoring order in China. The Manchus agreed with great alacrity, marched into China, recovered Peking, and kept it (1644), placing the grandson of Nurhachu on the throne with the reign title of Shun-chih (q.v.). China now came in contact with Russia, who by 1638 had reached the port of Okhotsk on the Pacific. As this place was situated too far north for a serviceable port, Russian encroachments began in the Manchurian region, with the purpose of securing control of the Amur River, then entirely within Chinese territory. Border conflicts between Manchu and Muscovite were ended in 1681 by the Treaty of Nerchinsk, a disastrous diplomatic defeat for Russia, as she was forced out of the Amur region and had to content herself with the Argun River and the Stanovoi Mountains as the boundary. A century and a half passed before Russia advanced again, this time with complete success. Taking advantage of China's complications with Great Britain and

France, Russia in 1860 by the Treaty of Peking acquired that part of Manchuria lying on the left bank of the Amur and east of the Usuri, extending to the Pacific and south to modern Chosen. This region is to-day known as the Primorsk, or Maritime Province, of Siberia. The cession of this important territory left the boundaries of Manchuria substantially as they existed in 1895.

In the Chino-Japanese War, 1894–95, Japan invaded Manchuria and captured Kaiping and Port Arthur. The Treaty of Shimonoseki, concluding the war, stipulated in part that Japan was to receive the Liaotung Peninsula, which includes Port Arthur, but Japan was forced to retrocede the peninsula to China through the collective intervention on China's behalf of Russia, France, and Germany. In return for this signal service, Russia in 1898 demanded and received of China a 25-year lease of Port Arthur and Talienwan (Dalny) and extensive railway and mining privileges throughout Manchuria. The Boxer Rebellion in 1900 furnished Russia the excuse to send military forces into Manchuria. These forces Russia promised to withdraw in three installments, which was not done, and Russian activities plainly pointed to the conversion of the temporary occupation of Manchuria into permanent possession. It was the fear of Russian absorption of Manchuria, and ultimately Korea, which drove Japan into the Russo-Japanese War of 1904–05. (See RUSSO-JAPANESE WAR for full treatment of the Manchurian situation at that time.) By the Treaty of Portsmouth, Sept. 5, 1905, Russia and Japan both agreed to evacuate Manchuria excepting Kwantung (the Liaotung Peninsula), where Japan succeeded to the lease and rights of Russia with China's consent, which was given Dec. 22, 1905. Russia also transferred to Japan that part of the Manchurian Railway which runs south from Changchun (Kuanchengtze) to Port Arthur. Since the war Russia and Japan have been very active in Manchuria, in the north and the south respectively. They have practically divided the three provinces into Russian and Japanese "spheres of influence." In 1909 Philander C. Knox, American Secretary of State, tried to prevent this by proposing the neutralization of the Manchurian railways, these to be bought by the Great Powers collectively and held by them until the expiration of the leases. His scheme met with no favor and only succeeded in drawing Russia and Japan closer together than ever. The result is apparent to-day, with Russia supreme in economic and strategic control of northern Manchuria and Japan likewise in the southern region. It is problematical what the situation will be in the future when the leases and railways are due to revert to the Chinese government and China is supposed to have regained full political and economic control.

MANCHURIAN DEER. See SIKA.

MANCHURIAN SUBREGION. One of the zoögeographical subdivisions of the Palearctic region, which embraces China north of the Yang-tse, Manchuria, Korea, and Japan (q.v.). It has the fauna of the plains and seacoasts of eastern Asia. The mountains which separate it from the Siberian region permit many northern animals to stray far eastward along their lofty spurs; and the Manchurian fauna penetrates far westward along the intervening valleys and foothills. Its exclusive forms are few, and these are allied to Palearctic groups, and differ decidedly from the Oriental region to the southward. See DISTRIBUTION OF ANIMALS, and accompanying maps.

MANCHUS, măn′chōōz. A people whose representatives sat upon the throne of China from 1644 to 1912. They belong by language and physical type to the Tungusic group of Siberian (Mongolian) peoples, whose habitat includes a large portion of northeastern Asia between the Yenesei and the coast of the Pacific. The Manchus are rather tall, with mesocephalic head form. Up to the period of their conquest of China and their subsequent assumption to a large extent of Chinese culture, the Manchus seem to have been a rude, energetic, and warlike people, who adapted themselves to the tasks of empire with the skill and enthusiasm of a vigorous and healthy race of primitive habits and culture. Their original home seems to have been at the base of the Shan-a-lin, or Long White Mountains, north of Korea (modern Chosen). From this locality they gradually spread through conquest, at first as independent tribes and later united under the command of one chieftain, Nurhachu (born 1559). This leader carried on an incessant warfare against China, and reduced almost all of Manchuria, removing his capital from Mukden to Liaoyang. At his death in 1626 his fourth son succeeded him, exacted tribute from Korea in 1627, and advanced into Liaosi and Mongolia. In 1644 the Manchus were invited to Peking by the Chinese general Wu San-Kwei to assist him in crushing a rebellion. They captured Peking and remained there, establishing upon the Chinese throne the *Ta Ching* or "Great Pure" dynasty, which reigned from 1644 to 1912. The grandson of Nurhachu became the first Manchu Emperor of China, and took the name of Shun-chih (q.v.). From Shun-chih to Hsüan-t'ung, who abdicated in 1912, there were 10 Manchu emperors of China.

The Manchus followed a wise policy of conciliation in China, adjusting themselves to Chinese civilization, law, and culture. Especially did they encourage the Chinese system of education and the literati. With the exception of the first two emperors they were not well disposed towards intercourse with the rest of the world, and they strove to keep China as hermetically sealed as possible against new ideas from outside. The Manchus have never equaled the Chinese in scholarly or literary ability. They were at best a warlike race ruling China, and when their warlike nature was weakened their hold on the country became precarious. Long before the end in 1912 there were many rebellions against them, one of which, the Taiping (q.v.), from 1850 to 1864, came near ending Manchu rule at that time. As it was, their overlordship would have terminated much earlier than the recent revolution but for the Chinese respect for authority as formerly personified in the Emperor.

There are not many Manchus left to-day. In Peking they had largely intermingled with the Chinese, and in Manchuria they exist only in scattered communities. Provision is made in the new Chinese constitution for equal treatment of Manchus and Chinese in the Republic. The Manchu language is now practically dead. The alphabet consists of 25 letters (based on Mongol), six of which are vowels. They consist of certain marks and curves written on either side of a vertical stem, thus forming syllables, which are ranged in columns and read from left to right.

The Manchus introduced the queue into China, which to the Chinese, from a badge of servitude, became a mark of loyalty and veneration. The queue was abolished by the revolutionists in 1911. Foot binding was never practiced among Manchu women. From the Chinese the Manchus have received the form of Buddhism they profess, through which, however, the original Shamanism frequently crops out.

Plath, *Die Völker der Mandschurei* (Göttingen, 1830–31); Schrenck, *Reisen im Amur-Lande* (St. Petersburg, 1881–91); James, *The Long White Mountain* (London, 1888); Ross, *Manchus; or, The Reigning Dynasty of China, their Rule and Progress* (ib., 1891); Sir Alexander Hosie, *Manchuria, its People, Resources, and Recent History* (Boston, 1910); Giles, *China and the Manchus* (Cambridge, 1912); P. H. B. Kent, *The Passing of the Manchus* (London, 1912). For Manchu language and grammar, consult Adam, *Grammaire de la langue Mandchou* (Paris, 1873).

MANCINELLI, män′chė-nĕl′lė, Luigi (1848–1921). An Italian composer and operatic conductor, born at Orvieto. He taught himself to play the piano and later studied the cello under Sbolci in Florence. In 1870 came the turning point in his career, with his engagement for the orchestra of the opera at Rome, under the famous Terziani. Within five years he had succeeded Terziani, and when the directorship of the Bologna Conservatory became vacant, in 1881, he was offered and accepted the position, and so revolutionized its methods that it rapidly rose to rank with the greatest music schools of Europe. His European fame as a conductor began at Drury Lane, London (1886–88), and was enhanced during his five years at Madrid in a similar capacity. At the conclusion of his service with the Madrid opera, he came to New York, where he was principal conductor at the Metropolitan Opera House from 1893 to 1902. Thereafter he directed in the principal opera houses of Italy, chiefly in Rome, and was an indefatigable and most influential worker for the art of Wagner. His compositions comprise: overture and entr'acte music to Cossa's *Cleopatra* and *Messalina;* the operas *Isora di Provenza* (1884), *Ero e Leandro* (1897), *Paolo e Francesca* (1907); the overtures *Isaia* (1887) and *Sant' Agnese* (1905). It is on his ability as a conductor that his fame chiefly rests.

MANCINI, mȧn-chē′nė. The name of five sisters, nieces of Cardinal Mazarin, who played a brilliant part at the French court during the early reign of Louis XIV. They were born in Rome and spent their childhood in that city, but between 1647 and 1653 were summoned to Paris by Mazarin, who undertook the charge of their education and advanced their fortunes at court. This "battalion of nieces," as Michelet calls them, comprised: (1) Laure (1636–57), a girl of amiable and pious disposition and the companion of the boy King Louis XIV. She became the wife of Louis de Vendôme, Duke de Mercœur, and died in childbed six years later. She was the mother of Louis, Duke de Vendôme, one of Louis XIV's greatest generals. (2) Marie (1639–c. 1715); she came to Paris in 1653, and after some time was attached to the court. (3) Olympe (1640–1708); she came to France in 1647, and her education was largely superintended by the Queen mother, Anne of Austria. She was witty and piquant and took a leading part in all the gayeties of the court. (4) Hortense (1646–99), the most beautiful and admired of the sisters. She came to France in 1653, and after a two years' education in a convent was introduced into the royal circle. (5) Marie Anne (1649–1714), the wit of the family, and for a time the soul of all courtly festivities. She married in 1662 Godefroy Maurice de la Tour, Duke of Bouillon, became the patroness of La Fontaine, and made her home a meeting place for celebrities like Corneille and Molière. Consult: Renée, *Les nièces de Mazarin* (Paris, 1856); Chatelauze, *Louis XIV et Marie Mancini* (ib., 1880); H. N. Williams, *Five Fair Sisters* (New York, 1906).

MANCINI, Pasquale Stanislao (1817–88). An Italian statesman and jurist, born at Castel Baronia, near Ariano, in Campania. He studied law at Naples, became professor of law at the university there when quite young, and in 1848 was deputy to the Neapolitan Parliament. On account of his liberal opinions he had to flee Naples, went to Turin in 1849, and was made professor of public law at the university. In 1860 he was elected to the Italian Parliament as a member of the Left. When the Italian Kingdom became a fact Mancini was made Minister in Rattazzi's cabinet. After 1872 he was professor of criminal law at Rome. From 1876 to 1878 he was Minister of Justice and Education under Depretis, and in this office procured the abolition of capital punishment, and showed himself an opponent of the Clerical party. From 1881 to 1885 he was Minister of Foreign Affairs, but had to resign on account of his colonial policy. Mancini was a brilliant orator and a zealous advocate of Italian unity.

MAN′CIPLE'S TALE, The. One of Chaucer's Canterbury Tales. It is the story of the white crow turned black by Apollo for telling of the falseness of his wife, Coronis. It is found in Ovid's *Metamorphoses*.

MANCO CCAPAC, män′kō kȧ-päk′. The founder of the Inca dynasty in Peru, and according to tradition the survivor of four brothers, children of the sun, who came forth from the apertures of the dawn, i.e., from the eastern cordilleras of the Andes. He established himself at Cuzco with his sister wife, Mama Oclla Huaco. He was supposed to have shown the people improvements in agriculture and architecture, and to have taught them the sciences and arts, by which means he acquired the leadership which was transmitted to his descendants.

MANCO IN'CA (?–1544). The last Peruvian ruler to oppose successfully the Spanish invasion of his country. He was the son of Huayna Ccapac (q.v.). Succeeding to the native headship after the murders of his brothers, Huascar and Atahualpa (1533), he tried to make friendly terms with the Spaniards, placing himself in their power. Pizarro treated him courteously and supervised his installation in accordance with the native rites. Manco, with a body of natives and Spanish auxiliaries, defeated the remnants of Atahualpa's armies, who were still maintaining the fight for independence against the Spaniards. Further acquaintance with his new friends changed his ideas, however, and in April, 1536, Manco left Cuzco and called upon his people to rally and drive out the Spaniards. A fierce attack was made on Cuzco, during which most of the city was burnt, but the followers of Pizarro successfully defended their position. After a siege of five months the Inca was compelled to retire, in order that his people might go home to sow their fields. He established himself at the stronghold of Ollantay-Tampu, in the Yucay valley. There Pizarro tried to capture him, but the attack was repulsed, and the natives followed the Spaniards back to Cuzco, which was again besieged. The arrival of Spanish reënforcements from Mexico and Panama and the return of Almagro from Chile compelled the Inca to withdraw to the wild mountainous country between the rivers Apurimac and Vilcamayu, where he maintained his independence with a small body of his relatives and followers. Here several renegade Spaniards sought refuge with him, and one of these killed the Inca during a sudden brawl, in 1544.

MANDÆ'ANS (from Mandaic *mandā*, knowledge), also called NASOREANS and, less correctly, ST. JOHN'S CHRISTIANS. A religious sect which has flourished in Babylonia very possibly since the beginning of the Christian era. At the present time the adherents of this faith live in the marshy lands near Basra and in Khuzistan. The number of Mandæans was estimated by Petermann in 1854 to be about 1500, but Siouffi in 1880 found about 4000. Thévenot in 1663 counted 3279 families. Ignatius a Jesu asserted that there were 20,000 to 25,000 families in 1652, but he may have included many heretical Christians. At the time of Mohammed they were probably a considerable body, forming the most important part of the Sabians or Baptists (from the Aramaic root *saba*, to baptize), to which the Elkesaites and Hemerobaptists also seem to have belonged. From them Mohammed may have adopted the custom of washings before the daily prayers. Hence he and his followers were long known as Sabians. As a people possessing a written revelation they were accorded by Mohammed the same privileges as Jews and Christians. The Mandæans have nothing in common with the pagans of Harran, who to gain for themselves these privileges falsely claimed to be Sabians and were thus permitted to continue their idolatrous practices. Whether the Mandæans designated themselves in any other way than as *Mȧndaye*, i.e., *gnostikoi* (those who have the knowledge), is not certain. Their religious views are known through their extant writings. Among these the most important are *Ginza* (The Treasure), also called *Sidra rabba* (The Great Book); *Sidra de Yahya* (The Book of John), also called *Derashe de malke* (Discourses of the Angels); and *Ḳolasta* (Purity), a collection of baptismal songs; there are also *Diwan* (The Book), *Asfar Malwasha* (Signs of the Zodiac), and a number of incantations, some of them discovered at Nippur. *Ginza* was published by Norberg from a Paris codex dated 1633, and more critically by Petermann from another Paris codex dated 1560. *Ḳolasta* was published by Euting from several manuscripts, the oldest of which was written in 1570. *Sidra de Yahya*, *Diwan*, and *Asfar Malwasha* exist only in late manuscripts. A large collection of incantations, all of recent date, have been published by Pognon. All of these writings are of composite authorship; they represent a long development, and the Mandæan religion is a mixture of many elements. The earliest parts of *Ginza* apparently present a purely pagan gnosticism, as yet uninfluenced by Jewish or Christian thought. Lagarde has pointed out that some of the sections showing familiarity with Judaism go back to a period when animal sacrifices were still practiced and the Christians were regarded as merely a Jewish sect, consequently to the first century A.D. Nöldeke has indicated some parts that must have been composed in the Sassanid period (226–651). But even *Ginza* and *Ḳolasta* contain many elements that are evidently later than Mohammed. It is probable that certain elements were at first borrowed from Christianity. Much old Babylonian and Persian speculation has also survived in Mandæanism. According to the original polytheistic doctrine, the soul belongs to a better world, the realm of the "first life," and is only temporarily attached to the body in the world of matter, in which the gods of light have chained the powers of darkness. This world is the creation of the powers of the "second life," who try to drag men down from the world of light. Through *Manda de Hayye*, the personified "knowledge of life," the soul may be brought back to its pristine state. An important symbol and means of purification is the holy lustration. The relations between these Baptists on the Euphrates and John the Baptist have not yet been cleared up. He maintains a position of honor among them, and this led to the name Christians of St. John, given by missionaries of the seventeenth century. Notwithstanding the Christian elements in their faith, they are bitterly hostile to certain Christian doctrines as well as to the Jews. They declare that *Jeshu Meschicha* (Jesus the Messiah) and his mother, *Rucha Ḳudscha* (the Holy Ghost), are evil spirits and the authors of all false religion. Efforts on the part of Nestorian missionaries to convert them may have caused this hostility. They have bishops, priests, and deacons, and admit women to these offices. They have a sort of Lord's Supper and observe Sunday and fasts. They are polygamous and command the marriage of priests.

The Mandaic language belongs to the Aramaic branch of the Semitic family. It is only dialectically different from the language of the Babylonian Talmud, and probably represents the Aramaic speech of Babylonia from Upi to the Persian Gulf. Its syntax is particularly important. Even its vocabulary shows less foreign influence than the kindred Aramaic tongues. A grammar has been written by Nöldeke. The script is a form of the Syriac, closely akin to that which was carried to Manchuria and Mongolia by Mesopotamian missionaries. It seems to have been in use in the seventh and eighth centuries. The Mandæans now use the Arabic language. *Ginza* was translated into Latin by Norberg. Tychsen and De Sacy translated some sections of *Kolasta* and *Sidra de Yahya*. Large parts of *Ginza* have been rendered into German by Brandt. Some of the incantations have been translated by Pognon. The religion has been best described by Brandt.

MANDALAY, măn′dȧ-lā. The capital of a district and division of Upper Burma, India, on the left bank of the Irrawaddy, 350 miles north of Rangoon, with which it has railway, river, and telegraphic communications, and 17 miles above Amarapura, which it replaced in 1857 as the capital of the former Kingdom of Burma (Map: Burma, C 2). Since the British occupation in 1885 the town has been greatly improved, a disastrous fire in 1892, which destroyed nearly the whole of the city, facilitating the necessary measures. It covers an area of 6 square miles and is traversed by fine, shady, and well-lighted thoroughfares. It consists of the walled town, now called Fort Dufferin and used as the cantonment, inclosing the palace, the former residence of King Theebaw, the government house, and the hall of justice, and the extramural town with its numerous temples, pagodas, and monasteries, and the Zagyo bazar noted for its wares and the heterogeneous and polyglot character of its habitués. Perhaps the most remarkable feature of the town is the Kuthodaw, or 450 Pagodas, consisting of the Buddhist scriptures engraved on 450 stones inclosed in as many pagodas ranged around a square of about half a mile in extent. Silk weaving is the chief industry. Pop., 1891, 188,815; 1901, 183,816; 1911, 138,299.

MANDA′MUS (Lat., we command). An extraordinary legal remedy afforded by a writ or command of a court of competent jurisdiction issued in the name of the state, directed to an inferior court, an officer, corporation, or individual, requiring it or him to perform a public duty as required by law. The writ of mandamus was originally a command of the sovereign and was without judicial character, hence it is that it is called a prerogative writ. As a purely prerogative writ its issuance was wholly a matter of discretion with the sovereign, and with its assumption of a judicial character it remains to some extent prerogative in the sense that it is granted at the discretion of the court. By discretion, however, is meant sound legal discretion; and the writ is now regarded as a remedy to be granted in a proper case according to well-settled legal principles. The writ is a purely legal and not an equitable remedy, although, in commanding things to be done, the court acts *in personam*, an exception to the usual practice of courts of law. See EQUITY.

The writ of mandamus will be issued only when the petitioner is without adequate remedy by an action at law, and then only to compel the performance of an official public duty which the officer, after demand, has refused or failed to perform. The duty must also be clear and undoubted, and it must be purely ministerial and not judicial or discretionary in character, for the court will not substitute its discretion for that of the officer the validity or propriety of whose act is in question.

The procedure upon the application for the writ and its issuance is now almost wholly regulated by statute. Consult: H. G. Wood, *Treatise on the Legal Remedies of Mandamus and Prohibition* (3d ed., Albany, 1896); T. C. Spelling, *Treatise on Injunctions and Other Extraordinary Remedies* (2d ed., Boston, 1901); W. F. Bailey, *Treatise on the Law of Habeas Corpus and Special Remedies* (2 vols., Chicago, 1913).

MAN′DAN. A city and the county seat of Morton Co., N. Dak., 5 miles northwest of Bismarck, on the west bank of the Missouri River and on the Northern Pacific Railroad (Map: North Dakota, D 4). It is in a lignite coal-mining region, has deposits of clay, and carries on a trade in live stock, wool, dairy products, and grain. There are railroad machine shops here, the city being a division point on the Northern Pacific. Mandan has the State Reform School and a government experimental station. In the vicinity are prehistoric mounds of considerable interest. The city adopted the commission form of government in 1907. The water works are under municipal ownership. Pop., 1890, 1328; 1900, 1658; 1910, 3873.

MANDAN. A noted and interesting tribe of Siouan stock (q.v.), now settled on Fort Berthold Reservation, at the junction of the Little Missouri with the Missouri River, North Dakota, in alliance with the Arikara (Ree) and Minitari (Hidatsa or Gros Ventres, q.v.). They formerly lived much farther down the Missouri and were then a numerous and influential people, but their decline has been almost without parallel for its rapidity. About 1773 they occupied nine villages on both sides of the Missouri about the entrance of Heart River. Pressed by the Sioux and wasted by smallpox, they soon afterward moved up the river, combining now into six villages. By 1804 they had again removed up the river, reduced now to two villages, and settled a few miles below the entrance of Knife River, in close neighborhood to their friends, the Arikara and Minitari (q.v.). Here they were found by the explorers Lewis and Clark, who wintered among them and have much to say of their friendly character. Here it was also that they were nearly exterminated in 1837 by the smallpox, which, brought first to their villages by a trading steamer, rapidly swept the whole plains, destroying thousands of victims and spreading death and terror among all the tribes from Canada to the Gulf. The Mandan were reduced in a few weeks from a tribe of about 1600 to a mere handful, reported, on what seems good authority, at 145 souls. Whatever may have been the true number, it was so small that they were lost sight of. The Arikara, who had lost about half their own number, moved into the untenanted Mandan villages, and for some years the Mandan tribe was thought by the traders to have become extinct. A few were still left, however, among the Arikara and Minitari, and with rare determination they set about building up again their shattered tribal structure. Within 10 years they were again a tribe, small but respected. In 1845 the Minitari moved up the river to the present location at Fort Berthold, where the Mandan soon afterward joined them, to be followed still later by the Arikara. They now number 209.

In spite of their migrations, the Mandan were not properly a nomadic people, but lived in stockaded villages of large and substantial circular log houses with earth-covered roofs, similar to those of the Pawnee and other sedentary tribes along the Missouri River. (See EARTH LODGE.) They were agricultural, raising corn, tobacco, and sunflowers, besides going out upon the plains to hunt buffalo at regular seasons. They tattooed upon the face and breast, and were usually designed as "tattooed people" in the sign language. They used a peculiar circular boat, known as a bull boat and much resembling a tub in shape, made of buffalo skins stretched over a willow frame. Among all the tribes they were noted for their elaborate ceremonials and particularly for the terrible self-imposed tortures of the great Okeepa rite, described by Catlin. The light complexion and hair frequently seen among them, the principal ground on which Catlin and others have tried to establish a theory of Welsh origin, are due partly to a species of albinism by no means rare in some tribes, but more to admixture of white blood. Consult: R. G. Thwaites, *Early Western Travels*, vols. xxii–xxiv (Cleveland, 1905); Will and Spinden, "The Mandans: A Study of their Culture, Archæology, and Language," in *Peabody Museum of American Archæology and Ethnology, Papers*, vol. iii (Cambridge, Mass., 1908); R. H. Lowie, *Societies of the Mandan and Hidatsa Indians* (New York, 1913); George Catlin, *North American Indians* (2 vols., Philadelphia, 1914).

MANDARA, mȧn-dä'rȧ, or **WANDALA**, wȧn-dä'lȧ. A small negro kingdom in central Sudan, Africa, south of Lake Chad and tributary to Bornu (q.v.). It is a wild and densely forested mountain region. Its population numbers about 250,000 and consists of negroes professing Islam and advanced industrially to some extent. The chief town, Doloo, is fortified. Since 1893 Mandara has belonged partly to the German and partly to the British sphere of influence.

MAN'DARIN (Portug. *mandarim*, from Malay, Hind. *mantri*, councilor, from Skt. *mantrin*, councilor, from *mantra*, council, from *man*, to think). Any Chinese official, civil or military, who is entitled to wear a button on his official hat. The term is entirely unknown to the Chinese, who speak of them officially as kwan. There are nine ranks, each distinguished by a different-colored ball or button placed on the apex of the cap or hat, by a peculiar emblazonry on the breast (a bird in the case of a civil officer, and a wild beast in the case of military men), and a different clasp on the girdle. A mandarin is not allowed to hold office in his native province; he is not allowed to marry in the jurisdiction under his control, nor own land in it, nor have a near relative holding office under him; and he is seldom continued in office in a station or province for more than three years. It is incumbent on every provincial officer to report on the character and qualifications of all under him. The Mandarin dialect was properly the language of the court. During the late Manchu dynasty it was Pekingese; in some preceding dynasties it was the dialect spoken at Nanking. With slight variations mandarin, or Kwan Hwa, is spoken over three-fourths of the country, as well as in Manchuria.

MANDARIN. See Colored Plate of CITRUS FRUITS.

MANDARIN DUCK. The mandarin duck (*Aix galericulata*) is one of the most exquisitely colored of birds. It is a comparatively small species, about the size of a teal, and is very closely related to the common wood duck (*Aix sponsa*) of the United States. A native of China, it has been introduced as a semidomesticated bird, for ornament, into Europe and the United States. It is beautifully variegated with green, chestnut, purple, and white, and fine black markings. In addition to the gorgeous coloration, certain peculiarities of plumage on the head, neck, and wings add greatly to the beauty. The mandarin duck is said to be remarkable for being monogamous, and for remaining paired throughout life; it is an object of veneration to the Chinese, as an example of conjugal fidelity.

MAN'DATE (from Lat. *mandatum*, command, from *mandare*, to command, from *manus*, hand + *dare*, to give). 1. In the civil law, an undertaking by virtue of which one becomes the gratuitous agent of another. The term is derived from the Roman law, under which the mandate was the first form of agency recognized.

2. At common law the term "mandate" is sometimes employed to designate bailment made for the sole benefit of the bailor. See BAILMENT. Consult the authorities referred to under the titles AGENT; BAILMENT.

3. In the law of procedure the term "mandate" is sometimes loosely applied to any judicial command.

MANDAUE, mȧn-dou'ȧ. A town of Cebú, Philippines. It is situated on the east coast near the north entrance to Cebú Channel, 4 miles northeast of the town of Cebú. The chief industry is rice culture. Pop., 1903, 11,078.

MANDAYA, mȧn-dä'yȧ. A wild Malay tribe in southeastern Mindanao. The Mandaya inhabit the greater part of the Pacific coast of Mindanao, the headwaters of the Agusan River, and most of the district between Davao Gulf and Butuan Province. In the latter districts they are known as Mansaka, Mangwanga, Managosan, and Pagsupan. The tribe as a whole has no ruler, but is divided up into small groups, each with its own chief or *bagani*. He is its supreme ruler, but has no power over other groups. To become a *bagani* it is necessary for a man to have killed a certain number of persons. Fights are frequent and are precipitated by an aspirant for *bagani* honors, or are caused because of a desire for slaves or revenge. The weapons used are shields, spears, knives, and daggers. This latter is the traditional weapon of the Mandaya, who never ungirds it unless he be in the company of only near relatives. In some regions bows and arrows are found, but they are not in common use.

Except in districts influenced by the white man these people build their houses high in the branches of trees, where they are safe from sudden attacks of enemies. The houses are generally surrounded by clearings in which a variety of vegetables are raised. However, these crops are usually so small that even with the addition of game and forest products there is a yearly period closely bordering on starvation. Consult F. C. Cole, "Wild Tribes of Davao District, Mindanao," in *Field Museum Publication 170* (Chicago, 1913). See PHILIPPINE ISLANDS.

MANDEL, män′del, EDUARD (1810–82). A distinguished German engraver, born in Berlin, where he studied at the Academy under Maré and Buchhorn. The success of his first important plate, after Hildebrandt's "The Warrior and his Child" (1835), brought him the commission from the Prussian Art Union to engrave "Lorelei" after Begas, and in 1837 his election to the Academy. He completed his studies in Paris (1839–40) under Henriquel-Dupont, and in 1842 was appointed professor at the school of engraving connected with the Berlin Academy, of which he became director in 1856. He was one of the chief masters of modern engraving in Germany, unexcelled as regards correct drawing, fine feeling for rendering color, and plastic vigor. His most admired plates include: "Van Dyck's Portrait of Himself" (1841); "Titian's Portrait of Himself" (1843); Van Dyck's "Charles I" (1850); "Frederick the Great"; Raphael's "Madonna Colonna" (1855) and "Madonna della Sedia" (1865); "La Bella di Tiziano" (1868); but above all Raphael's "Madonna di San Sisto," the crowning effort of his life, completed shortly before his death and superior to the best previous reproductions of that master's work. Consult Pietsch, *Eduard Mandel und seine Werke* (Berlin, 1883).

MANDELGREN, män′del-grān, NILS MÅNSSON (1813–99). A Swedish artist and critic, born at Ingelsträde (Skåne). He was a student at Stockholm, Copenhagen, Paris, and Rome, and afterward obtained a pension from the government for his archæological services (1873). In 1851 he went to Paris and there wrote his *Monuments scandinaves du moyen-âge* (1855–62). He did much to encourage industrial art in Sweden and assisted in the foundation of the Swedish Society of Industrial Arts (1844). His other writings include *Samlingar till svenska konst- och odlinghshistorien* (1866) and *Atlas till Sveriges odlingshistoria*, a large work to contain 1200 plates with text, of which four parts appeared in 1877–84. For its continuation he willed money and his collections to the University of Lund.

MANDELKERN, män′del-kĕr′n, SOLOMON (1846–1902). A Russian Hebraist. He was born near Dubno, Volhynia, studied at the rabbinical schools of Vilna and Zhitomir, and took courses in Oriental languages at St. Petersburg and jurisprudence at Odessa, after which he received the degree of Ph.D. from the University of Jena. For seven years (1873–80) he was assistant rabbi at Odessa, and thereafter, except for a visit to the United States in 1900, lived at Leipzig. His literary work began in 1866 with a biblical poem ("Bat Sheba") which attracted considerable attention. After that he wrote many historical articles, satires, and epigrams for the Hebrew periodical *Ha-Shahar*. A collection of these, entitled *Hizzim Shenunim*, appeared in Vilna in 1875. His Zionist poems, *Shire Sefat Eber* (2 vols.), beautiful expressions of enlightened patriotism, were published in Leipzig in 1882 and 1889. His history of Russia, *Dibre Yeme Russia* (1876), enjoyed greater popularity than it merited. But his Hebrew-Latin Biblical Concordance (1896), which was 20 years in preparation, is a most scholarly work; indeed it is still the best of its kind. His other works include a Russian-German dictionary, a history of Russian literature, and numerous translations.

MANDELSTAMM, män′del-shtäm, LEON (1809–89). A Russian Hebraist and educator, born in the Province of Kovno and educated at the universities of Moscow and St. Petersburg. He traveled much and gained an intimate knowledge of European languages. In 1846 he became secretary of a rabbinical commission at St. Petersburg appointed to consider ways and means of educating the Jews in Russia. In this capacity he edited and published numerous textbooks suitable for Jewish schools, superintended a large body of teachers, and directed the opening of new schools. On leaving the government service in 1857 he went abroad and settled in Berlin, where most of his writings were published. These include: *Biblische Studien* (2 vols., 1862); *The Rascals of Saratov* (1863), an exposé of the scandalous ritual murder trial of 1857; *The Jewish Family* (1864), a dramatic novel in verse; *Stimmen in der Wüste* (1880). Mention should also be made of his Hebrew-Russian and Russian-Hebrew dictionaries (2 vols., 1859–60) and of his Russian translation of the Bible (1869). After a very brilliant career Mandelstamm spent the last years of his life in poverty and oblivion. His library forms the nucleus of the Jewish section of the New York Public Library.

MANDER, män′dĕr, KARL VAN (1548–1606). A Flemish painter and author. He was born in Meulebeke, near Courtrai, of a noble family, and received an excellent education. He studied art and poetry under Lucas de Heere in Ghent, and painting with Vlerick in Courtrai, and spent three or four years (1573–77) in Italy, mainly at Rome, working with Spranger. At Amsterdam he established with Goltzius an art school, of which Franz Hals was the most famous pupil, and he became head of a circle of poets. His literary activity almost entirely overshadowed his paintings, which are scarce, artificial, and of no great excellence. Among them are a "Deluge," at Schleissheim; "Portrait of a Man," in Vienna; and possibly "Juda and Tamar," in Brunswick. His original poetry was printed in 1597 under the title *De gulden harp*. He translated Vergil's *Bucolics* and *Georgics* (1597), and 12 books of the *Iliad* from the French (1611). But his most important work was *Het schilderboek* (The Book of Painters) (1604), a biographical dictionary of early Netherlandish and German painters. Although filled with unreliable anecdotes and lacking in sound criticism, it is nevertheless, in the absence of more reliable accounts, an invaluable source of information for Flemish and Dutch painting of the sixteenth century. New editions were printed at Amsterdam in 1617 and 1764; a French version at Paris in 1884. The best and most complete edition, with German translation and comments, is by Floerke (2 vols., Munich, 1906). Consult the work just cited and Plettinck, *Studien over Karel van Mander* (Ghent; 2d ed., 1887).

MAN′DERSON, Charles Frederick (1837–1911). An American soldier and politician, born in Philadelphia. He removed in 1856 to Canton, Ohio, where, in 1859, he was admitted to the bar, and at the outbreak of the Civil War enlisted in the Federal army. He rose to the rank of brigadier general of volunteers, resigning in April, 1865, because of wounds. He was twice elected prosecuting attorney of Stark County. In 1869 he removed to Omaha, Neb., and was for six years city attorney, and was a member of the Constitutional Convention in 1871 and again in 1874. He served as a Republican in the United States Senate from 1883 to 1895, and was President pro tempore of the Senate for the Fifty-first and the Fifty-second Congresses (1891–95). Afterward until his death he was general solicitor for the Burlington Railroad System west of the Missouri River. In 1899 he was elected president of the American Bar Association.

MANDEVILLE, măn′de-vĭl, Bernard (?1670–1733). Author of the *Fable of the Bees*, born in Dort (or Dordrecht), Holland, about 1670. In a thesis maintained at Leyden, March 23, 1689, and entitled "De Brutorum Operationibus," he argued that brutes act automatically—a theory of Descartes and of the older theology. Having taken his degree in medicine at Leyden, he settled in London as a physician. Never gaining much practice, he received, it is said, a pension from Dutch merchants, and turned a more or less honest penny by advocating dram drinking, to the advantage of distillers, who recognized his services by *douceurs*. He died in London, Jan. 21, 1733. His famous book, a doggerel pamphlet, first appeared under the title *The Grumbling Hives, or Knaves Turned Honest* (1705). It was republished in 1714, with the title *The Fable of the Bees, or Private Vices Public Benefits.* A second edition with additions (1723) was presented as a nuisance by the grand jury of Middlesex. A second part appeared in 1728. Mandeville attempted to prove, perhaps with irony, that "private vices are public benefits"; that waste, luxury, and profligacy are good things for a state. His audacious thesis led to a sharp controversy, in which Bishop Berkeley took a hand (*Alciphron*, 1732). Among Mandeville's other works are: *Esop Dressed, or a Collection of Fables Writ in Familiar Verse* (1704); *Free Thoughts on Religion* (1720); *An Enquiry into the Causes of the Frequent Executions at Tyburn* (1725). Consult P. Sakmann, *Bernard de Mandeville und die Bienenfabel-Controversie* (Freiburg, 1897), and J. M. Robertson, *Pioneer Humanists* (London, 1907).

MANDEVILLE, The Travels of Sir John. The title of a famous itinerary and collection of marvels, composed in the third quarter of the fourteenth century. The book opens and closes with delightful fragments of an apocryphal autobiography. The author claims to be one John Mandeville, born at St. Albans, who crossed the sea in 1322 and traveled through Tartary, Persia, Armenia, Africa, Chaldæa, Ethiopia, Amazonia, and India. On his return he stopped at Rome, where his "book was proved for true" by the Pope's council. He adds that he first wrote it in Latin and then turned it into French and English (1356). Until very recently all these statements were accepted as facts. It now seems clear that of the versions named the French (1371) is the oldest, and that from it were derived the others (early part of fifteenth century). Though the writer of the French original may have traveled in the East, his work is mainly a compilation from the travels of a German knight, William of Boldensele (1336), the journal of Friar Odoric (1330), the journey of Johannes de Plano Carpini, a papal envoy to the Tatars (about 1250), the history of the East by Hetoum, the Armenian (1307), other itineraries, and the mediæval *specula*. He drew upon Pliny, Solinus, Peter Comestor, Vincent of Beauvais, Brunell-Latine, and Jacques de Vitry. With little doubt the compiler of the work was Jean de Bourgogne dit à la Barbe (John of Burgoyne with the Beard), who died at Liége in 1372. He may have been the John of Burgoyne who likely quitted England in 1322 and had good reasons for living under an assumed name. The *Travels of Sir John Mandeville*, abounding in marvels, has delighted many generations. Of the work there are three English versions extant in at least 34 manuscripts. From the poorest were printed the 15 editions from 1499 to 1725. A better version, edited anonymously in 1725, was carelessly reprinted by Halliwell (London, 1839–68), and edited, with modern spelling, by Wright, in *Early Travels in Palestine* (ib., 1848); by Morley (ib., 1886); and, with three illustrative narratives, by Pollard (ib., 1900). A third version (northern dialect) was edited by G. F. Warner for the Roxburghe Club (Edinburgh, 1889). For a detailed study of the sources, however, the reader is referred to Albert Bovenschen's *Die Quellen . . . des . . . Mandeville* (Berlin, 1888).

MANDINGO, măn-dĭn̠′gō̍ (native name, *Mande-nga*). An extensive linguistic group of negroes more or less mixed with Hamites, dwelling in western Africa from the Senegal and Upper Niger to Monrovia, and numbering many millions. Physically they are spare and athletic; height, 1.700 millimeters, or 67 inches; the cranial index or proportion of head width to head length is 75.5–78.8. They frequently have aquiline noses and features distinct from the negro, though the hair is woolly. In their food, dress, and habitations they are far above savagery, and, under Arab teachers, have attained a certain degree of culture. The speech, called Mandi, is widespread and divided into many dialects, encircling Timbuktu and encroaching on Fulah and Hausa. About 700 years ago the Empire of Mali was founded by the ancestors of this people in the Upper Niger region, and under King Musa (1311–31) it covered the Gambia and Joliba basins. The Upper Niger tribes still call themselves Mali'-nke. In religion they are Mohammedan, having embraced that faith centuries ago and propagated it with great vigor. The Mandingos were divided into numberless tribes, each speaking its own dialect, and, through their lack of cohesion, they were conquered about 1500 by the Sonrhay. The English planted factories among them in 1618, but the expeditions into the Niger country ended in disaster. The French in the next century cut off the progress of the English. In 1862 the Gambia Mandingos waged a propaganda for Islam in which hundreds of settlements of pagan tribes on the Gambia were laid waste. Consult Sir H. H. Johnston, *Liberia, with an Appendix on the Flora by Otto Stapf* (2 vols., London, 1906), and Migeod, *The Languages of West Africa* (2 vols., ib., 1911–13).

MAN′DIOC. A starch-producing euphorbiaceous plant. See CASSAVA.

MAN′DOLIN (Fr. *mandoline*, from It. *mandolina*, dim. of *mandola*, *mandora*, variants of *pandora*, sort of lute, from Gk. *πανδοῦρα*, *pandoura*, Ossetic *fändur*, Armen. *pȧndiṙ*, stringed instrument, of Lydian origin). A musical instrument of the lute species. The body of the mandolin is shaped like a shell, formed of a number of narrow pieces of different kinds of wood, bent into the shape, and glued together. On the open portion of the body is fixed the sounding board, with a finger board and neck like a guitar. The Neapolitan mandolin, which is the most perfect, has four double strings, which are tuned, beginning with the lowest, g, d^1, a^1, e^2. The Milanese mandolin has six strings, tuned g, b, e^1, a^1, d^2, e^2. In Spain the mandolin is built with six double strings tuned g♯, c^1♯ f^1♯, b^1, e^2, a^2. There is also a Turkish mandolin, which has seven double strings. The kind of mandolin most generally used to-day is the Neapolitan. Its range is g–e^3. The strings are struck by a plectrum held in the right hand, while the fingers of the left hand regulate the notes as on the violin. As the instrument cannot sustain long notes, it is customary to play all such as a tremolo, just as is sometimes done on the piano by the rapid change of fingers on the same note. Although the mandolin has never been an orchestral instrument, operatic composers have occasionally employed it to obtain characteristic effects.

MAN′DRAKE (ME. *mandrake*, *mondrake*, *mandrag*, *mandrage*, *mandragora*, from Lat. *mandragoras*, from Gk. *μανδραγόρας*, *mandragoras*; influenced by popular etymology with *man* + *drake*, dragon, in allusion to the shape of the root and its supposed aphrodisiac qualities), *Mandragora*. A genus of plants of the family Solanaceæ. Two species are described by some botanists, the autumnal mandrake (*Mandragora autumnalis*), which flowers in autumn and has lanceolate leaves and ovate berries; and the vernal mandrake (*Mandragora officinarum*), which flowers in spring and has oblong-ovate leaves and globose berries. Both are natives of the south of Europe and of the East. The root, which often crudely resembles the human figure, is large and carrot-like, and from it the leaves spring with no apparent stem, and among them the stalked whitish flowers. The plant has a fetid, narcotic smell and is reputed poisonous. From ancient times aphrodisiac virtues have been ascribed to the mandrake, which was therefore supposed to cure barrenness. (See Gen. xxx. 14–16.) In the United States the name mandrake is often applied to the May apple (*Podophyllum peltatum*), a low-growing perennial plant, the fruiting stem of which divides about a foot from the ground, each branch bearing a large peltate leaf between which is a white flower succeeded by the yellow, fleshy fruit, about the size of a plum. Single flowerless stems bear peltate, seven to nine lobed leaves. The dried rootstock is used in medicine. It has alterative, cathartic, and emetic properties.

MANDRAKE (*Mandragora officinarum*).

MANDRIL, or **MAN′DREL** (from Fr. *mandrin*, mandril, from Lat. *mandra*, Gk. *μάνδρα*, stall, bed for insertion of the stone of a ring). A bar of metal very slightly conical or tapering inserted in a hole in the centre of a piece of work to hold it during the process of turning, as in a lathe, or to enable work to be done upon the outer surfaces of an article while it is held or kept from deformation. Mandrils are much used in forging, sheet-metal working, spinning, and similar processes.

MAN′DRILL. A baboon (*Cynocephalus mormon*, or *Papio sphinx*), the largest of the tribe, and perhaps the ugliest in features and disposition. It is nearly related to the drill, and its characteristics are fully described under BABOON. This animal inhabits west Africa, ranging from Senegambia to the Congo. Although it was known to the ancients, we are ignorant of most of its life history. It goes in bands, and the adults with canine teeth 1½ inches in length are very dangerous, especially to unarmed travelers. They are omnivorous, insects and fruit forming the chief articles of their diet. The mandrill can be tamed when taken young and a few which have been kept in European zoölogical gardens have shown under training much intelligence, but few pleasant traits. See Plate of BABOONS.

MANDURIA, mȧn-dōō′rē̇-ȧ. An ancient town in the Province of Lecce, south Italy, situated about 27 miles west of Lecce (Map: Italy, F 4). It has remains of ancient walls and produces olives, wine, grain, and fruit. The place is of Greek origin. Pop. (including Uggiano Montefusco), 1901, 13,113; 1911, 14,031.

MANDVI, mänd′vē′. A seaport of the native State of Cutch, Bombay, India, on the northern shore of the Gulf of Cutch, 180 miles southeast of Karachi (Map: India, A 4). Though there is no regular landing place, boats of any size can land at the sandy beach, and large vessels find secure anchorage in the offing. Mandvi has direct steamship communication with Bombay and is the outlet for a large area. Pop., 1891, 38,155; 1901, 24,683; 1911, 24,235.

MAN-EATER SHARK. A shark which is known or believed to devour men; specifically, the great "white" or "blue" shark (*Carcharodon carcharias*, or *rondeleti*) of the family Lamnidæ. This is one of the largest of the sharks, reaching a length of 30 or 40 feet. It frequents all temperate and tropical seas, and is occasionally taken on both the Atlantic and Pacific coasts of the United States. Its body is stout, and the caudal fin large and strong, giving great swimming power; the nose is square and pointed, the eyes prominent, the mouth very large and armed in both jaws with five rows of triangular teeth, which are peculiar in being serrated. In a specimen 36½ feet long, it is recorded, the teeth measured 1¾ inches across the base. There have frequently been dredged in the central Pacific *Carcharodon* teeth 4 inches across the base, indicating sharks more than twice as large; and it is believed that the owners of these teeth were living within a comparatively recent period. The color of the skin is by no means white, but of the hue of lead, with the tips of the pectoral fins black. This monster ranges the seas, seizing and devouring whatever it is able to overcome; a specimen taken in California had a young sea lion weighing 100 pounds in its paunch. Like other sharks, they follow ships for many days, feeding upon the offal thrown overboard and upon other fishes attracted by the same bait. That the larger ones might easily bite off the leg or devour the whole body of a man is not to be doubted; and unquestionably many such casualties have occurred to persons in tropical seas, although experienced swimmers, such as the pearl divers, profess to fear them little, being able to frighten them away, or avoid their rush, and even to stab them to death with a knife.

The earliest remains of this genus of sharks have been found in the Upper Cretaceous beds of Texas. In the Eocene marls of the Atlantic and Gulf coasts, especially in New Jersey and North Carolina, the teeth of *Carcharodon* are quite abundant and form an important source of the phosphate on account of which the deposits are mined. These fossil teeth often attain a size of 6 inches in width at the base and 6½ inches in height. This implies an owner fully 100 feet in length. Contemporary with this predecessor of the present species was another, distinguished by having a little projection on each side of each tooth near its base, and this species attained a length of 50 or 60 feet, and must have aided its larger relative in clearing the Miocene ocean of *Zeuglodon* and other great marine reptiles. They swarmed, as is known from the frequency of their teeth in the Tertiary deposits of many parts of the world, and seem to have been especially numerous along the southeastern coast of North America. The teeth of these, as well as of modern sharks, also abound on the floor of the deeper parts of the present oceans. See Plate of Sharks.

MANED WOLF, or Red Wolf. An extraordinary wolflike animal (*Canis jubatus*), regarded as the only true wolf in South America, and held by some naturalists to be entitled to generic distinction. It inhabits Brazil, Paraguay, and northern Argentina, but does not extend south of the borders of the pampas. It is about the size of the common wolf, but not so heavy, its height being due to its long, ungainly legs, which give it a peculiar stilted appearance. (See Plate of Wolves and Wild Dogs.) It has a rather slender, pointed head, long ears, and comparatively short tail. The general color is bright yellowish red, with a black patch on the nape of the neck, another on the lower jaw, and one on each foot, forming conspicuous black "stockings." This aspect and its habits seem to remove it from the company of the true wolves and place it nearer the fox dogs. (See Fox Dog.) It never assembles in packs, but lives in the forest in pairs and hunts entirely alone. It is nocturnal, secretive, timid, and rarely seen, and is feared by nobody. It will sometimes attack deer or sheep, but lives mainly upon small rodents. It also catches birds, reptiles, insects, and even eats fruits. An interesting account of this animal in captivity, accompanied by portraits, was written by Joseph Gleeson, in the *Century Magazine* for September, 1902.

MANÉN, mȧ-nān′, Juan (1883–). A Spanish violinist and composer, born at Barcelona. His progress in music was so rapid that his father exhibited him as a piano prodigy. Having studied the violin under D. Alard, he suddenly appeared as a violinist, and met with such success that in Germany he was compared to his famous countryman Sarasate (q.v.). Likewise he attracted much attention as a composer, not only in Spain, but perhaps to even a greater degree in Germany, where he resided at different times for protracted periods. His works comprise: the operas *Giovanna di Napoli* (1903), *Acté* (1903), *Der Fackeltanz* (1909); the symphonic poem *Nueva Catalonia;* a violin concerto; a suite for violin and piano; and a number of exquisite miniatures for violin and orchestra.

MANES, mā′nēz (Lat. nom. pl., OLat., *manis*, *manus*, good, in full, *Di Manes*, the good gods, deities whom the living have no need to fear so long as they appease them with proper offerings. Perhaps, however, the designation is euphemistic, like Eumenides, q.v.). A somewhat indefinite appellation given by the Romans to the powers of the lower world. In the earlier religious conception the term seems to be used without special reference to the souls of the departed and to denote rather the deities concerned with the realm of the dead. They are, therefore, invoked in all ceremonies which concern the dead, and on such occasions as the "devotion" of P. Decius Mus to the gods of the lower world, or in curses. Later, as early as the time of the Twelve Tables (q.v.), the dead were thought of as deified; we now find the Manes conceived of as deified souls like the earlier *Di parentum*, and on monuments the letters D. M. (*Dis Manibus*) apparently dedicate the spot to them. To the Manes offerings were made at funerals, and at such commemorative ceremonies as the *Parentalia*, held by the Romans in February in honor of their dead ancestors. These offerings included libations of wine, warm milk, oil, honey, and the blood of black victims (pig, sheep, bull—the *Suovetaurilia*). Consult: W. H. Roscher, *Ausführliches Lexikon der griechischen und römischen Mythologie*, vol. ii, part ii (Leipzig, 1894–97); W. W. Fowler, *Roman Festivals* (London, 1899); Georg Wissowa, *Religion und Kultus der Römer* (2d ed., Munich, 1912).

MANES. The founder of Manichæism. See Mani; Manichæism.

MANET, mȧ′nȧ′, Edouard (1832–83). An epoch-making French painter, the pioneer of Impressionist painting (q.v.). He was born at Paris, Jan. 23, 1832, and belonged to a family of magistrates, who desired him to follow the same career. After completing his studies at the Collège Rollin, at Paris, he was sent to Rio de Janeiro in the hope of changing his determination to become a painter. Persisting in his design, upon his return to Paris in 1850 he entered the studio of Couture, with whom he worked five years. He then traveled in Germany, Holland, and Italy, studying the old masters, especially the works of Tintoretto at Venice, whose influence is evident in a series of religious pictures painted about this time. But a more important influence upon his work was that of the Spanish painters, particularly of Velazquez, whom he afterward studied in the Prado. He eventually evolved a style of his own, which broke absolutely with tradition and revolutionized modern painting. One chief characteristic of this style is the substitution of actual values of color (q.v.), as they are in nature, for the relative or corresponding values of the studio. Another was a broad execution, in which he gave the predominating local color, ignoring the minor variations, thus giving the general effect, to the effacement of detail and modeling. The tendency of his painting was constantly towards lighter color, and he finally adopted the plein-air technique, particularly from about 1870; thereafter most of the products of his brush were open-air subjects.

Among the best known of his early works are: "The Artist's Parents" (1860); "Boy with a Sword" (1860, Metropolitan Museum, New York); "Guitar Player" (1860, Osborn collection, New York); "Dead Toreador" (Widener collection, Philadelphia); "Music in the Tuileries" (1862, Dublin Gallery); "Execution of Emperor Maximilian" (1868–69, Mannheim Gallery); "The Balcony" (1869, Luxembourg). His "Breakfast on the Grass," in which a nude female figure is contrasted with clothed men, raised a storm of misdirected indignation. His other works include: a "Dead Christ and Angels" (1864, Havemeyer collection, New York); "Olympia" (1865); the "Garden" (1870, Havemeyer, New York), his first real plein-air painting; "The Good Beer" (1873, Arnold collection, Berlin); "The Opera Ball" (1873, Havemeyer, New York); "Argenteuil" (1874, Tournai Museum); the "Railroad" (1874); "The Laundry" (1875); "Nana" (1876); "Bar at Folies-Bergère" (1882); "Jeanne" (1882). Among his many portraits were those of Théodore Duret (1867, Petit Palais); Emile Zola (1868); the painters Eva Gonzalez (1870) and Berthe Morisot (1872, Dublin); "The Artist" (1875); Clémenceau (1879); Henri Rochefort (1881, Hamburg); Antonin Proust (1881); besides several of himself and his wife. He painted also, especially in the sixties, admirable still-life subjects, a number of which are in the possession of the Durand-Ruel Company, in New York and Paris. He also executed a number of pastels, and etched a series of his works (published 1874), besides illustrating Cros's *Le fleuve*, Champfleury's *Les chats*, and Poe's *Raven*.

Painting of so revolutionary a character raised much criticism, in which Manet's part was ably taken by his friend Zola. His choice of subjects from low life also militated against his popularity. The Salon was usually closed against him and he was forced to hold separate exhibitions. He did not receive the Legion of Honor till 1882, and not until after his death was his importance fully realized. He was a highly cultured man, of great wit and social charm. His death occurred at Paris, April 30, 1883.

Bibliography. The first and one of the best critical accounts of Manet's life and works is by his friend Théodore Duret, *Histoire d'Edouard Manet et de son œuvre* (Paris, 1902). Like that by another friend, Antonin Proust (ib., 1913), it is full of personal reminiscences. Soundly critical German monographs were written by Hugo von Tschudi (Berlin, 1902) and Meier-Graefe (Munich, 1912). Of great interest is Emile Zola, *Edouard Manet: Etude biographique et critique* (Paris, 1867). Other accounts are: Edmond Bazire (Paris, 1884); Gonse, *Gazette des Beaux-Arts*, vol. i (ib., 1884); Beckwith, in J. C. Van Dyke, *Modern French Masters* (New York, 1896); Etienne Moreau-Nelaton, *Manet, graveur et lithographe* (Paris, 1906); Laran and Le Bas, *Edouard Manet* (Philadelphia, 1912), containing a bibliography; Théodore Duret, *Manet and the French Impressionists*, translated by J. E. C. Flitch (London, 1912).

MANETENERI, mä′nå-tå-nā′rē. A tribe of Arawakan stock (q.v.) residing upon the Upper Purus and Juruá, southern affluents of the Amazon, on the Brazil-Bolivia frontier. They are a river people, constantly on the move in great canoes of cedar wood. They weave cotton cloth and use iron axes and fishhooks.

MAN′ETHO (Lat., from Gk. Μανεθών, *Manethōn*). The most important of all classical writers who have treated the history of ancient Egypt. He is said to have been a native of Sebennytus in the Delta, a high priest (of Heliopolis or Sebennytus), and scribe of the temples of Egypt; i.e., a president or secretary of the priestly assemblies. He appears as representative of the Egyptian priesthood and Egyptian learning under Ptolemy I Soter when he and the Athenian priest Timotheus were the only scholars able to identify as Serapis the statue of an unknown god brought from Sinope to Alexandria. It is certain that Manetho's principal work, the *Egyptian History*, was written, however, under Ptolemy II Philadelphus, as it contains a reference to the Arsinoite nome (i.e., the Fayum), and must therefore be later than 273 B.C., the date of the marriage of Ptolemy II with his sister Arsinoë. This history, in three books, has become famous, for it was the only work in Greek based on a full knowledge of the Egyptian sources. A more doubtful tradition states that Ptolemy II himself selected Manetho as the Egyptian scholar who possessed the most profound Greek scholarship and ordered him to write the history of the country. Manetho undoubtedly possessed as much knowledge of Egyptian history as could be expected of any Egyptian priest, and he followed chiefly the native sources, inserting occasional polemics against the errors of Herodotus and others. Nevertheless, his work is marred by the introduction of some mythological Greek names and other matters.

Manetho's work, now known only through a few bits of narrative in Josephus (*Against Apion*) and from tables of dynasties and kings in the Christian chronographers, does not seem to have been much read outside of Egypt, though it played an important part in the controversy between Josephus and Apion near the end of the first century A.D. Later the Christian chronographers made considerable use of it in arranging the biblical chronology, but it is questionable if they had the complete work. Thus, we have only a few passages of the history quoted in Josephus, and the chronological tables, e.g., in Julius Africanus and Eusebius, both tables preserved only in the work of George Syncellus of Byzantium (792 A.D.), and in the so-called *Excerpta Barbari* (in Latin). These extracts have come down to us in such a mutilated form that it is very difficult to form an opinion of the value of the original book. The earlier Egyptologists overrated the importance of this authority, and lately it has been treated with the greatest skepticism. Not only have the names and dates been corrupted to a large extent, but Manetho undoubtedly did not possess sufficient sources of information to make his book absolutely reliable. Nevertheless, we still retain his division of Egyptian history into 30 dynasties from Menes (before whom the fabulous reigns of gods, demigods, and manes are enumerated) to Alexander, although this division is recognized to be merely conventional in more than one case. The old discussion as to whether the dynasties of Manetho were all consecutive or whether some were contemporaneous has been settled in favor of the second theory, although it applies only to a few cases (e.g., dynasties 15 to 17). The Sothiac cycle of 1460 years (at the end of which the short civil year of the Egyptians and the correct astronomical or Julian calendar again coincided), followed by Manetho in his chronological arrangement, has been of little use to modern scholars, owing to the fragmentary condition of the extracts. It is often possible to correct the errors of Manetho by the aid of the monuments. Consult: Boekh, *Manetho* (Berlin, 1845); Unger, *Chronologie des Manetho* (ib., 1867); handy editions of the text in Bunsen, *Egypt's Place in Universal History*, translation, vol. i (London, 1848–67), and in C. Müller (ed.), *Historici Græci Minores* (2 vols., Leipzig, 1870–71). Manetho is said to have written also: *A Compendium of Natural Science; Concerning Feasts; On the Preparation of Kyphi* (i.e., aromatic frankincense). Whether these works were spurious, as is undoubtedly the *Apotelesmata*, an astronomical work of the Christian time, cannot be determined; another "Manethonian" book, the *Sothis* (i.e., dog star), is clearly spurious, as it is dedicated to the Emperor Augustus.

MANETTI, mȧ-nĕt'tē, GIANOZZO (1396–1459). An Italian humanist, born at Florence. He was educated for commercial affairs, but from 1421 identified himself with the literary life of the time, studying Greek and acquiring a knowledge of Hebrew then unusual. He served as Ambassador to the courts of Venice, Naples, Rome, and other Italian governments. His fame as an orator was great and many marvelous stories of his eloquence are preserved. The greater number of his discourses were pronounced in Italian, but were translated into Latin for publication. He became so influential that Cosimo de' Medici by oppressive taxes drove him from Florence. He was then attached to the service of Pope Nicolas V, and later of King Alfonso of Naples. His learning was extensive, and in his endeavors to effect harmony between Christian traditions and the rediscovered classical world he became one of the foremost exponents of the new learning. He lacked literary art, however, and his works are often verbose and platitudinous. Among his writings are translations into Latin of the ethical treatises of Aristotle, the Psalms, and the New Testament, and a lengthy polemic, *Contra Judæos et Gentes.* Consult Vespasiano da Bisticci, *Commentario della vita di Giannozzo Manetti*, edited by Frati (Bologna, 1893).

MAN'FRED (c.1232–66). King of Naples and Sicily from 1258 to 1266. He was a natural son of the Emperor Frederick II. On his father's death, in 1250, he received the Principality of Tarentum, and in the absence of his half brother, Conrad IV, acted as regent in Italy. After Conrad's death he was acknowledged regent of Apulia for his nephew Conradin (q.v.). Pope Alexander IV caused a crusade to be preached against him, but Manfred, steadily pursuing his victorious career, became, in 1257, master of the whole Kingdom of Naples and Sicily. On the rumor of Conradin's death he was crowned King of Palermo, Aug. 10, 1258, and immediately afterward was excommunicated by the Pope, together with his adherents, among whom were the first prelates of the Kingdom. Manfred invaded the papal dominions, levied heavy contributions from them, and made himself master of the whole of Tuscany. His power now seemed secure, especially as he married his daughter Constance to Peter of Aragon, while he himself married the sister of the Greek Emperor Theophilus. His government was at once mild and vigorous; he founded many schools, built towns and harbors, and labored in many ways for the improvement of his Kingdom. But this tranquillity was not of long duration. Pope Urban IV renewed the excommunication against him and his friends, and bestowed his dominions as a papal fief on Charles of Anjou, the brother of Louis IX of France. Manfred, though at first successful in the war which ensued, was at last defeated and slain in a bloody battle at Benevento, Feb. 26, 1266. His widow and children were savagely treated by the French, the daughter being imprisoned for 17 years and the sons dying in captivity. His body, as that of an excommunicated person, was interred on the battlefield under a heap of stones. Consult: Schirrmacher, *Geschichte der letzten Hohenstaufen*, vol. iv (5th ed., Leipzig, 1878); A. Karst, *Geschichte Manfreds vom Tode Friedrichs II. bis zu seiner Krönung* (Berlin, 1897); Karl Hampe, *Urban IV. und Manfred* (Heidelberg, 1905); Jordan, *Les origines de la domination angevine en Italie* (Paris, 1909). See CHARLES OF ANJOU.

MANFRED. A dramatic poem by Byron (1817). Count Manfred, a kind of magician, dwelt in the Alps in solitary misery. Superhuman in his nature, he was so in his suffering. Schumann composed a musical setting of the poem, which was performed under Liszt's direction at Weimar in 1852. A version of *Manfred* was produced upon the stage in England in 1863.

MAN'FREDO'NIA, *It. pron.* män'frȧ-dō'nē-ȧ. A town in the Province of Foggia, Italy, 23 miles northeast of the city of Foggia, on the Gulf of Manfredonia (Map: Italy, E 4). It is strongly walled, and an imposing castle protects its port, which is accessible only to small vessels. Two miles west of the town are the ruins of ancient Sipontum, of which the cathedral of Santa Maria Maggiore, a twelfth-century edifice in the Romanesque style, has been partly restored. In the vicinity of Manfredonia are some remarkable salt lakes; figs, almonds, and carobs are extensively exported. It is the seat of an archbishop. The town was founded by Manfred in 1263, but its industrial growth was checked by the Turks, who pillaged it in 1620. Pop. (commune), 1901, 12,188; 1911, 13,692.

MANGABEY, măn'gȧ-bĭ (a geographical name in Madagascar, erroneously applied by Buffon to an animal which is not found in the island). Any one of a group of eight or nine species of West African monkeys forming the genus *Cercocebus*, which is related to the guenons on one side and to the macaques on the other. They are distinguished by peculiarities of dentition, by the backward direction of the hairs of the crown, and strikingly by having white eyelids, wherefore they are frequently called white-eyelid monkeys. One well-known species, common in zoölogical gardens (where it is hardy and develops many amusing and gentle traits), is the sooty mangabey (*Cercocebus fuliginosus*, or *æthiops*). It is sooty black in color and has the singular habit of carrying its tail always thrown forward over its back. See Plate of MONKEYS OF THE OLD WORLD.

MANGALDÁN, män′gȧl-dän′. A town of Luzon, Philippines, Province of Pangasinán, situated near the south shore of the Gulf of Lingayén, 13 miles east-northeast of Lingayén (Map: Luzon, C 2). It is connected with Dagupán by highroad and a branch of the Manila-Dagupán Railroad. Pop., 1903, 15,841.

MANGALORE, măŋ′gȧ-lōr′, or **MANGALUR**, măŋ′gȧ-lo͞or′. The capital of the District of South Canara, Madras, British India, 407 miles south-southeast of Bombay, on the Arabian Sea (Map: India, C 7). The residential section of the city is pleasantly situated on several hills which afford an extensive view of the sea and the thickly forested surrounding region. It has a German mission where instruction is given in the different crafts, and is the seat of a government college and the Jesuit College of St. Aloysius, both of which are connected with Madras University. The town has a large Roman Catholic population, mainly Goanese, and is the seat of a bishop. A large trade is carried on in coffee, nuts, and pepper, and various grades of cloth are manufactured. The harbor is a backwater formed by the junction of two small streams and affords good anchorage. The port has an annual trade to the value of 65 lacs of rupees, mainly in coffee. Mangalore is renowned for the brave resistance its little garrison offered the army of Tippu Sahib in 1782–83. Pop., 1891, 40,922; 1901, 44,108; 1911, 48,412.

MANGAN, JAMES (1803–49). An Irish poet, born in Dublin and educated in schools of that city, at one of which a learned priest helped him to varied linguistic acquirements. For literary purposes he added Clarence to his given name. During 10 years, beginning in his fifteenth year, he served in a scrivener's office and for three years in an attorney's office. Thereafter he was employed for short periods in the Ordnance Survey Office and in Trinity College Library. For the rest he lived an erratic and precarious literary life, depending upon his pen for support, and sinking deeper and deeper with the years into indulgence in drugs and alcohol. He and Ferguson after him were the originators of a new Celtic movement. His poetry is exceedingly uneven: at his best—in 20 or 30 of his famous poems—he is second to none of the Irish poets who have written in English; in the large remainder of his work he is little more than a skillful versifier, and at times aridly rhetorical. The best of his poems—the splendid "Dark Rosaleen" among them—are based upon Gaelic originals or drawn from Gaelic sources. While he lived only one collection of his poems, *Anthologia Germanica* (1845), appeared. All his best work is found in: *Poems* (1859); *Essays in Prose and Verse* (1884); *Selections* (ed., Miss L. I. Guiney, 1897). Consult D. J. O'Donoghue, *Life and Writings* (London, 1897).

MANGANBLENDE, măŋ′gan-blĕnd. See ALABANDITE.

MAN′GANESE (Neo-Lat. *manganesium*, an arbitrary variant of *magnesium*, magnesium). A metallic element first isolated by Gahn in 1774. It is generally accepted that Pliny was acquainted with pyrolusite, or manganese dioxide, and assuming it to be a variety of magnetic iron ore, which was called *lapis magnesius*, he called the manganese compound *magnesia*. Basil Valentine and later chemists regarded the compound as an ore of iron, and mentioned its use in glassmaking under the name of *lapis manganensis*. That the compound really contains no iron was first shown by Pott in 1740, and later researches by Scheele and Bergman established the fact of its being a distinct chemical species. The name *magnesium*, at first applied to its isolated metal, was changed to *manganese* by Buttmann in 1808.

Manganese ores are found in many parts of the world. The occurrences of the United States may be grouped as follows: 1. Manganese ores, containing at least 35 per cent manganese. They are found most abundantly in the Appalachian and Piedmont regions of Virginia and Georgia, in the southern Mississippi valley, and on the Pacific coast. One of the largest mines, situated near Crimora, Augusta Co., Va., has been operated for nearly 50 years and is still productive. The ore occurs in pockets in a thick bed of residual clay, and is mined by the hydraulic process. 2. Manganiferous-iron ores, containing usually more than 5 per cent manganese and a variable proportion of iron. These are found chiefly in New England, the Appalachian region, and the Lake Superior iron district. 3. Manganiferous-silver ores, consisting of mixtures of manganese and iron oxides and hydroxides, with small amounts of lead and silver. While they occur both in the Rocky Mountain and Great Basin regions, Leadville, Colo., is the most important locality. 4. Manganese-zinc residuum, an artificial furnace product with manganese and iron, obtained from the zinc volatilization of New Jersey zinc ores. The production of spiegeleisen and ferromanganese in the United States in 1913 was 226,475 long tons. The imports were 128,147 long tons. Enormous deposits of manganese ore are found in southern Russia and in the State of Minas Geraes, Brazil. Small quantities of manganese are also present in certain mineral waters, in many plants, especially the cereals and vegetables used as human food, and it is a constituent of the sun's atmosphere. The metal itself is readily obtained by reducing the oxide with carbon or by heating manganese chloride with metallic sodium. Manganese (symbol, Mn; atomic weight, 54.93) is a very hard, grayish-white metal with a reddish lustre. It takes a high polish and is not malleable. Its specific gravity varies between 7.13 and 8. Its melting point is about 1897° C. (about 3447° F.). The metal itself has no uses, but forms valuable alloys with copper, iron, zinc, tin, aluminium, lead, magnesium, etc. Those with iron, containing from 8 to 20 per cent of manganese, are used in the manufacture of steel under the names of *spiegeleisen*, while those with 20 to 80 and even 90 per cent manganese are called *ferromanganese*. The presence of manganese in iron and steel is said greatly to increase their elasticity and hardness, and even

1 per cent of manganese will render cast steel more tenacious. Copper-manganese alloys are used in the manufacture of manganese bronze, manganese brass, and manganese German silver. Heusler's alloy is a peculiar magnetic alloy of copper, manganese, and aluminium.

With oxygen manganese forms several oxides, including a monoxide (MnO), a sesquioxide (Mn_2O_3), a dioxide (MnO_2), a trioxide (MnO_3), and a heptoxide (Mn_2O_7). Besides these a number of intermediate oxides are believed to exist. The most important of the oxides is the *dioxide*, or peroxide, which occurs native as *pyrolusite* and is the black manganese of commerce. The *sesquioxide* of manganese, or manganic oxide, occurs in nature as the mineral braunite, or, in a hydrated form ($Mn_2H_2O_4$), as the mineral manganite. The *monoxide* of manganese, or manganous oxide, occurs in nature as the mineral manganosite, or, in a hydrated form (MnH_2O_2), as the mineral pyrochroite. It is the manganese salts corresponding to this oxide that are found, always together with iron salts, in mineral water and in the organisms of animals and plants. For the *trioxide* of manganese, see MANGANIC AND PERMANGANIC ACIDS.

In the formation of manganous and manganic salts the manganese acting as a metal unites with the halogens, with sulphur, selenium, nitrogen, phosphorus, arsenic, antimony, vanadium, boron, carbon, silicon, titanium, tin, and zircon. Manganese may also form double salts with the principal metals, and compounds of manganese with organic acids, as acetates, are known.

Uses. The greater part of manganese ore mined is used in the iron and steel industries. The ore used for alloys should have at least 40 per cent manganese and under .2 per cent phosphorus, but silica and other impurities can be eliminated in the smelting. If manganese is used as an oxidizer, the ore should contain a high percentage of manganese dioxide. Much is consumed for this purpose in the flint-glass industry, and the ore which has at least 80 per cent MnO_2 and under 1 per cent iron comes chiefly from the southern Caucasus Mountains, Russia, and Thuringia, Germany. For dry batteries high-grade pyrolusite with over 85 per cent MnO_2 is employed. The more siliceous and argillaceous types of manganese ore are employed for coloring pottery, tiles, and bricks. Some manganese ore is also employed as a flux in smelting lead-silver ores, especially when the ore itself contains some of the precious metals. The use of manganese is no longer important in the manufacture of chlorine or oxygen. Consult: L. L. Fermor, "Manganese Deposits in India," in *Geological Survey of India, Memoirs*, vol. xxxvii (Calcutta, 1909); E. C. Harder, "Manganese Deposits of the United States, with Sections on Foreign Deposits, Chemistry, and Uses," in *United States Geological Survey, Bulletin 427* (Washington, 1910); Roscoe and Schorlemmer, *Treatise on Chemistry* (5th ed., London, 1913); Talbot and Brown, *Bibliography of the Analytical Chemistry of Manganese* (Washington, 1913).

MANGAN′IC AND PER′MANGAN′IC ACIDS, H_2MnO_4 and $HMnO_4$, respectively. Two important acid compounds of manganese. The former is unknown in the free state, but is well known in the form of certain of its salts, termed *manganates*. The most important of these are the manganates of potassium (K_2MnO_4) and barium ($BaMnO_4$). Potassium manganate is obtained by fusing manganese dioxide with caustic potash and potassium chlorate or nitrate; on cooling the mass is dissolved in a moderate quantity of water and the solution is allowed to evaporate *in vacuo*. The salt thus obtained is unstable, being readily decomposed by acids, or even by an excess of water, into potassium permanganate (see further below), caustic potash, and manganese dioxide. It is this reaction that causes the well-known change of color in solutions of potassium manganate. The manganate of barium is obtained by heating barium oxide with manganese dioxide; it may be used as a green pigment. *Manganic anhydride*, or manganese trioxide (MnO_3), may be obtained by dissolving potassium permanganate in strong sulphuric acid and heating the solution.

Permanganic acid may be obtained in the uncombined state by the action of sulphuric acid on barium permanganate; but the resulting solution decomposes with extreme readiness and hence the acid cannot be isolated from it. The solution is deep red in color and has powerful oxidizing and bleaching properties. The most important among the *permanganates*, or salts of permanganic acid, is the permanganate of potassium ($KMnO_4$), which forms long prismatic crystals having a deep red color by transmitted light and a green metallic lustre. It may be prepared by heating one of the oxides of manganese with an alkali and potassium chlorate or some other oxidizing agent, and heating the resulting mass with water, when manganese dioxide is precipitated and potassium permanganate remains in solution. A method of preparation often employed consists in adding potassium chlorate to a solution of caustic potash, adding finely powdered mineral manganese dioxide to the solution, evaporating to dryness, heating the residue to a semiliquid condition, allowing to cool, dissolving the resulting mass in hot water, and passing into the solution a current of carbonic acid gas, until the transformation appears to be complete. The solution is then filtered through guncotton, concentrated by evaporation, and allowed to crystallize. Another method much used consists in preparing potassium manganate (see above) and exposing it to the action of acids. In the solid state, as well as in concentrated solutions, potassium permanganate is very readily decomposed. Mixed with sulphur and phosphorus, solid potassium permanganate can be ignited by striking. Mixed with charcoal, it can be ignited by moderate heating. Its saturated solution (one part in 15 parts of water at ordinary temperature) decomposes on the application of gentle heat and even on standing for some time at ordinary temperatures. Even in dilute solution potassium permanganate acts as a powerful oxidizing agent, and upon this are based many of its uses in medicine, analytical chemistry, and the arts. Sugar and many other organic substances are readily oxidized by it. Potassium iodide (in solution) is converted by it into potassium iodate. If a solution of potassium permanganate is mixed with one of peroxide of hydrogen (another oxidizing agent), the two substances give up part of their oxygen simultaneously, so that both are reduced at the same time. The oxidizing power of potassium permanganate is considerably increased in the presence of acids. Among the uses of the permanganate may be mentioned its use for the preparation of oxygen, its use as a bleaching agent, its use in the purification of water, ammonia, and carbonic acid gas, its use in photography, and finally its use as a disinfectant, deodorant, and antiseptic in medicine. It is employed as a deodorant for bedpans and as a wash for the hands, the solution commonly used being known as Condy's red fluid. In a very dilute form it may be used as a mouth wash or gargle and as an injection in cases of gonorrhœal and other morbid discharges. According to some authors, if given internally in the form of pills, potassium permanganate has an action much like that of the salts of iron. The *permanganate of sodium* is very similar to that of potassium and is prepared by an analogous method. In the arts sodium permanganate is often employed in place of the potassium salt, but the latter alone is employed in chemical analysis. *Permanganic anhydride*, or manganese heptoxide, Mn_2O_7, is extremely unstable.

MAN′GANITE (from *mangan-ese*, from Neo-Lat. *manganesium*, arbitrarily altered from *magnesium*). A hydrated manganese peroxide that crystallizes in the orthorhombic system. It is most frequently found in prismatic crystals, deeply grooved and grouped in bundles or sheaves. Manganite has a submetallic lustre and is dark steel gray to iron black in color. It usually occurs in veins associated with calcite and barite in the older rocks. Manganite is found in the Harz, Thuringia, Sweden, Norway, England, and in the United States at various localities in Michigan and Colorado. In common with other manganese minerals it is used in the manufacture of alloys, as spiegeleisen and ferromanganese, and as a coloring material in calico printing and dyeing, for coloring glass and pottery, and in the manufacture of paints.

MANGATAREN, mȧn′gȧ-tä′rĕn. A town of Luzon, Philippines, in the Province of Pangasinán. It is situated on the Agno River road, 18 miles south of Lingayén, on a tributary of the Agno Grande. Pop., 1903, 12,895.

MANGBATTU. See Monbúttu.

MANGE (OF. *mangeue*, *mangue*, *manjue*, *menjue*, itch, voracity, food, from Lat. *manducare*, to chew, devour). A disease of horses, dogs, and cattle, similar to scab in sheep and itch or acariasis in the human subject, resulting from one or more of four different kinds of minute mites which attack the skin, causing much irritation, heat, and itching and the eruption of minute pimples, with dryness, scurfiness, baldness, and bleaching of the skin. The treatment consists in destroying the mites and insuring the cleanliness and health of the skin, both of which objects are effected by washing the parts thoroughly every second day with soft soap and water and dressing daily with sulphur or mild mercurial ointments or with a solution containing four grains either of corrosive sublimate or arsenic to the ounce of water. Castor-oil seeds, bruised and steeped for 12 hours in buttermilk, are very successfully used by the native Indian farriers. Where the heat and itching are great, as is often the case in dogs, a few drops of tincture of belladonna may be added to the usual dressing, or applied with a little glycerin. Where the general health is indifferent, as in chronic cases, the patient should be liberally fed, kept clean and comfortable, have an occasional alterative dose of any simple saline medicine, such as nitre or common salt, and a course of such tonics as iron or arsenic. Cleanliness and occasional washing and brushing maintain the skin in a healthy state and thus prevent its becoming a suitable place for the mites. The most suitable and convenient method for treating the mange of cattle is to build large dipping vats and plunge the affected cattle into a dip containing lime and sulphur or tobacco and sulphur.

MANGEL-WURZEL, măṉ′g'l-wûr′z'l (Ger., beetroot), Mangel, Mangold, or Field Beet. A general name for the varieties of the common beet (*Beta vulgaris*), extensively grown in temperate climates, especially in Europe, for the feeding of cattle, sheep, and swine. Formerly only garden varieties of the beet were grown, but during the last century larger, coarser varieties suitable for feeding came into prominence. The different varieties of field beets are generally divided into four groups: first, according to their shape, which is either long or more or less globular; and second, their exterior color, red or yellow. The long red and long yellow varieties produce the heaviest yields, but are usually coarse and fibrous and of low feeding value as compared with other varieties. A number of varieties of this group with twisted roots are known as the oxhorn varieties; the intermediate forms, also known as gatepost varieties, have large oval roots with red, yellow, or orange skins. The tankard varieties, which are of uniform width except at the abruptly tapering extremities, are shorter than either the long or the intermediate varieties. The mangel-wurzel is best adapted to deep clayey loam soils, moist but well drained, well tilled, and rich in plant food. In countries where this root has a place in the rotation of crops a heavy dressing of barnyard manure is incorporated in the soil before planting the seed, which is done in early spring. Six or eight pounds of seed are used to the acre in drills about 2 feet apart, the distance between the plants in a row being about 1 foot. To insure quick and equal germination, the seed is often steeped in warm water before planting. Close planting gives smaller and relatively more nutritious roots. During the growing season the crop is hoed by means of the cultivator or the hand hoe to keep the surface loose and free from weeds. Since the roots are injured by frost, the harvesting should be done before freezing occurs, the roots being dug by hand or lifted with an implement designed for the purpose; and if properly harvested without bruising, which induces decay, and well stored in a cool cellar or in pits, they will keep till late in the spring. The yield usually ranges from 18 to 25 tons per acre. Mangel-wurzel have on an average the following percentage composition: water, 91.2; protein, 1.4; fat, 0.2; nitrogen-free extract, 5.4; crude fibre, 0.8; and ash, 1.0. Like most roots, they are very succulent. The food

MANGEL-WURZEL.

value is chiefly dependent upon the starch and other carbohydrates making up the nitrogen-free extract. Roots of all kinds are much more commonly fed in Europe than in the United States. In Great Britain they replace much of the forage and grain in the ration of stock, as much as 20 pounds being fed daily to sheep and 100 pounds to cattle. Mangel-wurzel are chiefly used in the United States to give variety to the ration and are fed in smaller quantities. They are most often fed to dairy cows, 20 to 30 pounds being a fair daily allowance. They are sometimes fed to sheep, and boiled and mixed with meal they furnish good feed for pigs. Like other roots, they should be sliced for sheep, and sliced or pulped for cattle. Some feeders believe that they are valuable not because they themselves induce greater gains, but because they stimulate the appetite for other feeds and tend to keep the animal in good physical condition.

MAN′GIN, Edward (1772–1852). A British writer, born in London. He attended Balliol College, Oxford, where he graduated B.A. in 1793 and M.A. in 1795. Entering the Irish church, he held prebendal stalls in Killaloe Cathedral and in St. Patrick's, Dublin, but, being provided with a comfortable income, he passed most of his time at Bath, where he became known as a conversationalist and writer, and where he died. Among his publications are: *The Deserted City, or Bath in Summer* (1805), a parody on Goldsmith's *Deserted Village; An Essay on Light Reading* (1808); *Utopia Found: An Apology for Irish Absentees* (1813); *An Intercepted Epistle from a Person in Bath to his Friend in London* (three editions, 1815); *Piozziana: Recollections of Mrs. Piozzi* (1833).

MANGIN, General Joseph. See Supplement.

MANGKASSARS. See Macassars.

MANGLE (Dutch *mangel;* connected with Ger. *Mange*, mangle, Icel. *mangi*, mangonel, from ML. *manganum*, from Gk. *μάγγανον, manganon*, instrument for throwing stones). A machine for smoothing linen and cotton goods, such as tablecloths, sheets, etc., after washing, by passing between rollers. See Laundry Machinery.

MANGO, măŋ′gô (from Malay *mañggā*, Tamil *mānk*, mango fruit), *Mangifera*. A genus of about 25 species of evergreen trees of the family Anacardiaceæ, natives of India and the Malay Peninsula. The common mango (*Mangifera indica*) is a spreading tree of rapid growth, which attains a height of 40 feet or more, but whose undivided trunk is rarely more than 10 feet long. The foliage is very dense, forming a welcome shade. Its leaves are entire, lanceolate, shining, 6 to 8 inches long. The flowers are rather small, reddish white or yellow, borne in dense panicles. The fruit is more or less kidney-shaped, smooth, varying in size and color with different varieties, and contains a large flattened stone nearly as long as the fruit. The shell of the seed is rough and fibrous; in some of the poorer varieties the fibres are very abundant and apparently make up a considerable portion of the fruit. In the choicer kinds the pulp is more solid and rather free of fibres. This tree exists in nature in India, where it extends up the Himalayas to elevations of 3500 feet or more. It has been extensively introduced into other regions, so that now it is cultivated in nearly all tropical and subtropical countries. In India there are said to be more than 150 cultivated varieties, the fruit of some weighing a pound or more. All parts of the tree have a turpentine fragrance, and in some varieties the flavor of turpentine in the fruit is very pronounced. Others are without it and are highly prized for desserts, being luscious, sweet, or with a slight acidity. The unripe fruits are used for pickles, sauces, etc., and the kernels are often roasted and eaten. They are nutritious and in times of scarcity are used as food by the poorer classes of India. The mango was introduced into Jamaica in 1782, and much attention is given its cultivation in that country. Its cultivation has been extended throughout the West Indies and to some extent in southern Florida and California. Eight-year-old trees in Florida have borne as many as 5000 fruits in a season. The trees are propagated either from seed or by inarching of choice varieties upon vigorous seedling stock. Of the other species *Mangifera fœtida*, called the horse mango, is a large tree native of Malacca and vicinity. The fruit, which has a peculiar characteristic odor and flavor, is highly esteemed by the natives, and is cultivated throughout India. *Mangifera oppositifolia*, by some botanists called *Boula burmanica*, is a wide-spreading lofty tree which grows wild in Burma. It bears an edible yellow fruit about the size of a large plum. There are numerous varieties, some of which are sweet, others sour. *Mangifera sylvatica* also bears an edible fruit esteemed by the natives in India. It is often dried and kept for medicinal purposes. The wood of the different species is gray, rather soft, and used for planking, doors, window frames, packing cases, canoes, and boats.

MANGO (*Mangifera indica*).

MANGO BIRD. A bird frequenting mango trees: (1) in Jamaica, a humming bird (*Lampornis mango*); (2) in India, an oriole (*Oriolus kundoo*).

MANGO FISH (so called because it makes its appearance in April, about the same time as the mangoes). A small perchlike fish (*Polynemus plebijus*) which abounds along the shores of southeastern Asia, and in India enters bays and river mouths at the season when the mango fruits grow ripe. It represents a distinct but small group of tropical fishes (Rhegnopteri), of which several species are known under the family name threadfins, or Polynemidæ. The most prominent among many distinguishing characters of the group is the fact that the actinosts of the pectoral fins are of three forms—two of them normal, supporting the pectoral fin; one longitudinal, without rays; and the fourth a plate on the coracoid supporting free and separate rays, three to 10 in number, according to the species. These free rays are filaments trailing from the throat, sometimes longer than the body, each under muscular control; and they serve as feelers, for these fishes not only creep about in muddy estuaries, but are nearly blind, owing to the normal growth of films over the eyes. Several species occur in tropical American waters. One (*Polydactylus virginicus*), the barbu or barbudo (q.v.) of West Indian fishermen, is an important food fish in Cuba, and was called mango fish in the old books. Consult A. C. L. G. Gunther, *Introduction to the Study of Fishes* (Edinburgh, 1880), and P. H. Kirsch, *Annals of the New York Academy of Sciences*, vol. v (New York, 1890).

MANGO GINGER. A tropical plant. See CURCUMA.

MANGOLD. See MANGEL-WURZEL.

MANGOLDT, män′gôlt, HANS KARL EMIL VON (1824–68). A German economist, born in Dresden. He studied law and political science at Leipzig, Geneva, and Tübingen, and in 1848 was appointed to prepare a history of the industries of Saxony, but was prevented by changes in the administration from carrying out the work. In 1852 he became editor of the Weimar *Gazette*, and in 1855 he published his *Lehre vom Unternehmergewinn*, in which he was the first to analyze fully the phenomena of business profits. In 1858 he became extraordinary professor of political economy at Göttingen and in 1862 was called to the chair of political and cameral science at the University of Freiburg. In 1863 he published his *Grundriss der Volkswirthschaftslehre*, a treatise of admirable clearness which ranks among the first German contributions to the theory of economics.

MAN′GON, or **MAN′GONEL.** A mediæval implement of warfare, similar to the ballista, used for throwing stones and other missiles. See ARTILLERY.

MANGONI, mȧn-gô′nė, or **ANGONI.** Zulu intruders into the Nyassa region, British South Central Africa. They number about 230,000 and are descendants of a Zulu tribe which migrated from Zululand and crossed the Zambezi about 1825, founding a kingdom southeast of Lake Tanganyika. Thence they migrated west of Lake Nyassa, where they established three separate kingdoms. These military migrations are characteristic of the Zulus, who have been the cause of far-reaching ethnic displacements in Africa. In their movements they eliminated the men, and by marriages with the women of the conquered tribes, themselves became greatly modified, especially in language. The aristocracy of the Mangoni perpetuate the Zulu customs, while their language is that of their mothers. Thus, they wear the apron of cat-tails and, when engaged in war, kilts of skin around the waist or over the left shoulder and a headdress of raven and cock feathers, and carry clubs and stabbing assegais, the shafts of the latter being ornamented with goatskin. The oval shield of antelope or cow skin, like that of the Zulu and Matabeles, is also carried. They wear a profusion of personal ornaments, strips of hide with long hair secured around the leg and upper arm, armlets of elephant toe nails and ivory, and charms in shells, antelope horns, or beaded leather cases. The Zulu head ring of plaited hair and wax is sometimes seen, and the ears are bored to hold blocks of polished wood or ivory. The Mangoni are fine specimens of men and carry themselves well. The chief owns the herds of cattle, while the flocks of sheep and goats belong to individuals. Their villages are large and are composed of circular wattle and daub houses surrounded by compounds fenced in with reeds. Their vegetable food consists of maize, sorghum, cassava, rice, millet, sweet potatoes, beans, and peas. Cotton, oil seeds, and tobacco are also raised. The rule of the chief is supreme, but there is a numerous body of *idunas* or councilors, whose advice is sought. These councilors are assigned to various districts, for which they are responsible to the chief. The clan system prevails. The religion of the Mangoni is the worship of ancestors, and in the cult ceremonies and offerings are made to appease them. Several grades of witch doctors are possessed of priestly authority; the chief is high priest by virtue of his office. Consult Robert Codington, in the *Geographical Journal* (London, 1898), and Sir H. H. Johnston, *British Central Africa* (ib., 1906).

MANGOON, MANGUN, mȧn-gōōn′. See OLCHAS.

MAN′GOSTEEN (Fr. *mangostan* [the tree], *mangonste* [the fruit], from Malay *mangonsta, mangis*, the native name), *Garcinia mangostana*. One of the most delicious of all fruits, produced by a slow-growing tree of the family Guttiferæ, a native of the Molucca Islands. The tree, which rarely exceeds 20 feet in height, has an erect tapering stem and a regular form. The leaves are 7 or 8 inches long, oval, entire, leathery, and shining; the flowers large, with corolla of four deep-red petals. The fruit, which is orange-like, dark reddish brown, spotted with yellow or gray, has a thick rind and like the orange is divided internally by thin partitions into segments. The pulp is soft and juicy, cooling, with a mixture of sweetness and acidity, and delicately flavored. The mangosteen is cultivated in Java and in the southeast of Asia, and has been successfully introduced into some other tropical countries.

MAN′GROVE (from Malay *mañggi-mañggi*, mangrove; influenced by popular etymology with *mango* and *grove*, in allusion to its spreading by the formation of new stems), *Rhizophora.* A genus of plants of the family Rhizophoraceæ, which consists of a few species of trees and shrubs, all tropical and natives of coasts, particularly about the mouths of rivers, where they grow in the mud and form a close thicket down to and within the sea, even to low-water mark. The coast and keys of southern Florida abound in mangroves. Most of the species send down roots from their branches, and thus rapidly extend over large spaces. The clublike seeds have the peculiarity of germinating while still attached to the parent branch, a long thick radicle proceeding from the seed and extending rapidly downward till the fruit falls off and is quickly embedded in the mud. The bark of the common or red mangrove is used in tanning. The red-flowered mangrove, *Lumnitzera*, of the family Combretaceæ, is often associated with the true mangroves. The tree is being planted along the embankments of the railroad that traverses the Florida Keys to protect them from storms. The wood is heavy, fine-grained, and strong, and is employed in boatbuilding, etc. See Plate of Magnolia and Mangrove.

MANGROVE (*Rhizophora mangle*).

MANGROVE HEN. In Jamaica, the long-billed rail (*Rallus longirostris*), of which the North American clapper rails are varieties. See Rail.

MANGROVE SNAPPER. A fish, the gray snapper (q.v.), so called in Florida and the Bahamas because the young abound in the protection of the mangrove trees which everywhere border the seacoast.

MANGROVE SWAMP. A plant formation common on seacoasts and tidal river shores in tropical and subtropical climates. The dominant vegetation consists of mangrove trees interspersed with plants of similar habit. The accumulation of débris and mud among the roots and trunks builds up the land so that bays are filled and river banks extended until the streams are restricted to narrow channels between dense walls of trees which completely conceal the shores.

MANGUIAN, mȧn′gē-än′, or **MANGYAN.** All the wild natives of Mindoro are known as Manguian. In reality they do not form a single tribe or stock. Those in the north and about Mount Halcon closely resemble the Negrito, both in physical type and culture, while in the vicinity of Bulalakao and southern Mindoro they are typical Malays, somewhat advanced towards civilization. The women of this latter group wear cloth skirts and sometimes upper garments of cloth, and some men are seen with shirts. Lances and iron knives are used to a considerable extent. The southern Manguian write their language with an alphabet, evidently of Indian origin, cutting the characters into the smooth outer surface of bamboo joints. See Philippine Islands.

MANGU KHAN, män′gōō kän. See Mongol Dynasties.

MAN′GUM. A city and the county seat of Greer Co., Okla., about 150 miles by rail west-southwest of Oklahoma City, on the Chicago, Rock Island, and Pacific and the Wichita Falls and Northwestern railroads (Map: Oklahoma, B 4). It is in a rich farming country, producing wheat, cotton, corn, and kaffirs, and has an oil mill and a flour mill. Mangum has adopted the commission form of government. Pop., 1900, 2672; 1910, 3667.

MANGUM, Willie Person (1792–1861). An American politician, born in Orange Co., N. C. He graduated from the University of North Carolina in 1815 and was admitted to the bar in 1817. In 1818–19 he served in the General Assembly and was elected by that body judge of the Supreme Court in 1819, but resigned the next year. He served as a member of the United States House of Representatives from 1823 to 1826, when he again became judge. He was a presidential elector in 1829 and in 1831 became a member of the United States Senate. At the request of the Legislature he resigned in 1836, and the next year he received the 11 electoral votes of South Carolina for President. In 1840 he was returned to the United States Senate in place of Bedford Brown, who had also been requested by the Legislature to resign, and served until 1853, when the Whig party was practically disintegrated in his State. In 1842 he was elected president of the Senate to succeed Samuel L. Southard, of New Jersey, and served until 1845. During his senatorial service he was one of the leaders of the Whig party.

MANGUN, mȧn-gōōn′. See Olchas.

MANGWANGA, mȧn-gwäng′gȧ. See Mandaya.

MANHAT′TAN. A city and county seat of Riley Co., Kans., 51 miles west of Topeka, on the Kansas River, at the mouth of the Big Blue, and on the Union Pacific and the Chicago, Rock Island, and Pacific railroads (Map: Kansas, F 4). The State Agricultural College, opened in 1863, is situated here, and the city contains also the Sacred Heart Academy, Carnegie library and fine courthouse, high school, and Federal buildings. Manhattan is the commercial centre for a farming, fruit, and stock-raising district, and has white limestone quarries, a foundry, flour mills, ice plant, and agricultural machine works. The water works are owned and operated by the municipality. Manhattan has adopted the commission form of government. Pop., 1900, 3438; 1910, 5722.

MANHATTAN COLLEGE. A Roman Catholic institution in New York City, under the control of the Brothers of the Christian Schools. It was opened in 1849 as an academy for young men under the name of the Academy of the Holy Name, and was incorporated under its present name in 1863. It has an arts and a science department, conferring the degrees of B.A. and B.S. Besides the college proper there are academic and commercial departments. A course in civil engineering, leading to the C.E. degree, is also offered. In 1913–14 the registration was 270 and the faculty numbered 28. The college library contained 23,300 volumes. The president in 1914 was Rev. Brother Edward, F.S.C.

MANHATTAN INDIANS (native name = the island of hills). An Indian tribe of the Wappinger confederacy which at the time of discovery occupied Manhattan Island and portions of both the Bronx and Long Island. Consult E. M. Ruttenber, *Indian Tribes of the Hudson River* (New York, 1872), and Alanson Skinner, "Manhattan Indians," in *New York State Museum, Bulletin 158* (Albany, 1912). See MAHICAN.

MANHATTAN ISLAND. An island at the head of New York Bay, forming the borough of Manhattan in New York City and containing the commercial and financial nucleus of the metropolis, together with its main residence portion (Map: New York City, Greater New York, E 5). It lies between the Hudson River and the East River; Spuyten Duyvil Creek and the Harlem River separate it from the mainland on the north and northeast. The island, with tapering north and south extremities, a few hundred yards wide, is 13½ miles long, with a maximum width, at Fourteenth Street, of 2¼ miles, and an area of 22 square miles. It has a wharfage front of 22 miles, with a depth of water sufficient for the largest vessels. The Brooklyn Bridge, the Manhattan Bridge, the Williamsburg Bridge, and the Queensboro Bridge connect it with Long Island, and several bridges span the Harlem River and Spuyten Duyvil Creek; numerous ferries and tunnels communicate with the adjacent shores. The surface is undulating and rocky, in the north rising from the Hudson to an altitude of 238 feet at Washington Heights, but sloping abruptly towards the east, where is a level stretch formerly known as the Harlem Flats. Farther south the elevation continues as a central ridge, with a gentle slope on either side. Extensive leveling was necessary in laying out the streets. With the exception of the Harlem plain and an extensive bed of beach sand to the south and east of City Hall, the island is chiefly composed of crystalline Archean rocks with intercalated veins of gneiss, mica schist, and hornblende, overlaid by generally shallow glacial drift deposits. The greater part of the city is built on the rock foundation; pile foundations, however, are resorted to in the deeper glacial deposits and in the beach sand. Peter Minuit, the first Dutch Governor-General, is said to have received Manhattan Island in 1626 for barter to the value of about $25. See NEW YORK CITY.

MANI, mä′nē, also called MANES and MANICHÆUS (c.216–277). A Persian sage, founder of a religious and philosophical system which spread widely and lived long, especially in its western forms. The most valuable accounts of Mani's life are found in Mohammedan histories. He was born near Ctesiphon in Mesopotamia, where he received his education. His father, Fatak, was connected with the Mughtasilah, a South Babylonian sect of "baptizers," akin to the Mandæans (q.v.) and perhaps also to the Elkesaites (q.v.). Towards his thirtieth year Mani began the new religious movement which was to bear his name, preaching at the court of the Persian King, Shapur I. He claimed that he received divine revelations, and that he was the final prophet of God to the world. Not meeting with great success at court, he undertook a series of missionary journeys, penetrating into Turkestan, India, and China. He also sent out disciples to preach his doctrines. After spending many years in missionary labor, Mani returned to Persia, where he now won converts even at the royal court. But the Magians (the Persian priesthood) rose in opposition, and he was imprisoned, but managed to escape. After the death of Shapur Mani returned to the capital and was received with favor by the new King, Hormuz I. But the Magians renewed their attacks, and after some years of conflict secured his condemnation during the reign of Bahram I. Mani was crucified and his body was flayed and exposed to public contempt. His followers suffered bitter persecution.

Mani is reported to have been a man of great and varied ability along several lines, e.g., in the art of painting. He wrote in the Syriac and Persian languages, but used an alphabet of his own invention, which continued in use among his followers. His works, which were known to the Mohammedan historians, but have since been mostly lost, included the *Book of Secrets*, describing certain Christian sects of the East; the *Book of Precepts for Hearers*, the most widely current of his writings, probably to be identified with what Augustine calls the *Epistola Fundamenti;* and a *Holy Gospel* (perhaps not its actual title, though it is so called), a work written in Persian while Mani was in retirement in Turkestan. He also wrote several shorter treatises and numerous letters.

Bibliography. Among the most important sources for Mani's life are the Arabic *Fihrist* by Abulfarag an Nadim (tenth century), edited by Flügel (Leipzig, 1871–72); the Greek *Acta Disputationis Archelai*, edited by Routh, in *Reliquiæ Sacræ*, vol. v (Oxford, 1848), translated into English in the *Ante-Nicene Fathers*, American edition, vol. vi; and Eusebius, *Ecclesiastical History*, vii, 31. In Latin, the works of Augustine are valuable for western Manichæism; consult the *Nicene and Post-Nicene Fathers*, first series, vol. iv (edited by P. Schaff). For fragments of Manichæan works recently discovered, consult Kugener and Cumont, *Recherches sur la Manichéisme*, ii (Brussels, 1908), and "Un traité manichéen retrouvé en Chine," translated by Chavannes and Pelliot, in *Journal Asiatique*, series 10, vol. xviii; series 11, vol. i (Paris, 1911–13). In general, consult De Beausobre, *Histoire critique du Manichéisme* (Amsterdam, 1734); St. Augustine, *Writings in Connection with the Manichæan Heresy*, translated by Richard Stothert (Edinburgh, 1872); Konrad Kessler, *Manichäische Religion: Forschungen über die Mani* (Berlin, 1889); P. E. More, "Influence of Hindu Thought on Manichæism," in *American Oriental Society, Journal* (New Haven, 1896); Rochat, *Essai sur Mani et sa doctrine* (Geneva, 1897); Kessler, *Mani* (Berlin, 1899); Adolf Harnack, *History of Dogma*, vol. iii (Boston, 1903). For Mani's doctrine, see MANICHÆISM.

MA′NIA (Lat., madness). A form of insanity characterized by exaltation of emotional state, motor excitement, flight of ideas, great self-esteem, irritability, and impulsive reactions. See MANIC-DEPRESSIVE INSANITY.

MANIA, INDUCED. See IMITATIVE INSANITY.

MANICALAND, mȧ-nē′kȧ-lănd. Formerly a tributary state of Gazaland, and now divided between Portuguese East Africa (q.v.) and Rhodesia, forming in the latter part of the Province of Mashonaland (q.v.). It is very valuable for its gold fields and is traversed by the railway line from Beira to Fort Salisbury.

MANIC-DEPRESSIVE INSANITY. This is a form of mental derangement which usually occurs in one of two phases, to which respectively were given the terms "mania" and "melancholia." *Mania* of the older psychiatry comprises the excited and exalted cases, characterized by flushed face, flight of ideas, exaggerated well-being or irritability, impulsiveness, motor excitement, and emotional extravagance. Generally pleasurable and expansive ideas fill the mind. The patient imagines he is a person of great importance, wealthy, powerful, possibly a king or a queen. Distractibility is a prominent feature, and the flow of incessant language usually includes the expression of some ideas taken from the environment or descends into a tendency to senseless rhyming, the shifting and uncontrolled attention being easily influenced by surrounding people or chance conversation. The patient is oriented in many cases, occasionally somewhat clouded through failure of attention, and judgment is always disordered. Besides the euphoria (happy and elated condition) there is marked irritability. There is some eroticism in most cases and the moral sense is always diminished, the patient frequently indulging in alcoholic or other excesses, when previously of exemplary habits. The ordinary form of the manic type has been described. A milder form is that of *hypomania*, which is characterized by full orientation, absence of all delusion, excessive energy and constant overactivity, exalted good humor, great self-esteem, boisterous manner and language, and possibly irritability and outbreaks of anger.

The depressed type of manic-depressive insanity is characterized by a painful emotional state, despondency, weakening of the power of attention, sluggishness of the association of ideas, incomplete perception, constant indecision, and uncertainty. The patient may be conscious of his changed condition and of his weakened will. He may meditate suicide, under the delusion that he has committed some grievous sin or has some incurable disease. Hallucinations and delusions may be present. The condition described is the former *melancholia*, now understood to be a phase of the manic-depressive state. Physical symptoms are abundant, for the patient suffers from coated tongue, offensive breath, constipation, loss of appetite, sluggish surface circulation, small, slow pulse, loss of weight, and loss of sleep. In some cases there is a condition of stupor, into which the patient drifts, and during which all conscious and voluntary intellectual activity is suppressed, or the patient may be completely absorbed in frightful delusions and hallucinations. The stupor is an episode and does not represent a separate phase of the malady. Mixed states occur, such as *agitated depression*, *maniacal stupor*, and *unproductive mania*, which is characterized by exaltation and increased psycho-motor activity with difficult thinking (White). *Recurrent mania*, *recurrent melancholia*, and *periodic mania* belong under the head of manic-depressive insanity, as do *alternating insanity* and *circular insanity* (cyclothymia). In the last the patient experiences a brief depressed state followed by a maniacal outburst, which in turn is followed by depression, the cycle continuing without intervals. Involutional melancholia does not belong in this category. (See MELANCHOLIA.) Attacks of manic-depressive insanity last from a few days to many months. While the prognosis is bad for ultimate perfect recovery, the patient as a rule recovers from the separate attacks.

The treatment includes very little use of drugs. Hydrotherapy usually renders either drug or mechanical restraint unnecessary in the manic cases. The excited cases are to be guarded against exhaustion and well fed. Depressed cases must be under the eye constantly; sufficient food must be given (sometimes by means of the stomach tube), sufficient sleep must be secured, and the eliminative functions must be kept active. There is a tendency towards recovery, without intellectual enfeeblement, and a tendency towards recurrence. Over 60 per cent recover. This form of insanity constitutes about 12 per cent of all new admissions to hospitals for the insane, the manic cases predominating. See INSANITY.
